A question of synthetic preparations—namely, the substitution of products issued under protected names by preparations placed on the market by other firms but under their chemical names—is at the present moment exciting considerable interest in medical circles in Germany. The existing German Pharmacopœia (as well as the new edition) has adopted the full chemical name as a title in the case of official synthetic preparations. For instance, instead of antipyrin figures the formidable appellation "Pyrazolonum phenyldimethylicum." In the new Pharmacopœia, in the case of preparations such as novocaine (paramidobenzoyldiethylaminoethenol hydrochloride) it cannot be expected that these names will be received with enthusiasm by the practitioner. On the other hand, the sick-club organisations insist upon the prescribing of the cheapest drugs, and proprietary preparations are only allowed in special instances. Therefore the prescribers are enjoined to make use of the substitutes. Recently the organisation of Würtemberg sick clubs has adopted a plan to ensure the dispensing of substitutes only, even if the physician should make use of the protected name. A number of sick-club doctors have signed an agreement to the effect that they consent to the dispensing of a substitution product in all cases where they may make use of the registered trade-name, and the pharmacists have been supplied with a list of doctors who have consented to this arrangement, as well as of the preparations to which it applies. It remains to be seen what attitude the legal authorities and the firms with interests at stake are likely to take in this matter.

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1908.

(*Concluded from p. 1569.*)

The Health of the Native Army of India.

THE average strength of the native Indian troops, including those on duty in China and other stations outside India, was 126,975; their health statistics, while being more favourable than those of the European troops, were not so satisfactory as in 1907, when the rates of constantly sick, of invaliding, and of mortality were the lowest on record. The admission rate to hospital in 1908 was 674·4 per 1000, and the ratios of constantly sick, of deaths, and of invalids were 22·8, 7·41, and 6·63 respectively. The increased rate of admission to hospital was almost entirely due to the greater prevalence of malarial fevers, the admission rate from this disease alone being 266 per 1000, as compared with 225 in 1907, and among the more important diseases the admission rates from dysentery, diarrhœa, enteric fever, and cholera were also higher than in that year. The increased death-rate was due chiefly to a higher mortality from cholera, enteric fever, and pneumonia, but the death-rates from respiratory diseases and tubercle of the lungs were also higher than in 1907. The number of men invalided for discharge from the service was 842, as compared with 728 in 1907; these were mainly cases of tubercle of the lungs, injuries, debility, and malaria. Amongst regiments with a record of much sickness and mortality during the year were the 1–6th Gurkhas at Abbottabad, the 86th Carnatic Infantry at Secunderabad, the 112th Infantry at Nasirabad, the 1–2nd Gurkhas at Drosh, and the 41st Dogras at Cawnpore. The admission-rates in these regiments ranged between 420 and 1040 per 1000, and the death-rates between 21·46 and 33·16 per 1000. In the native army, as in the European, cholera was much more prevalent than in the previous year, 174 cases, with 116 deaths, being reported. Twelve cases, with 5 deaths, occurred among the native troops of the Mohmand Field Force. There were 103 admissions to hospital on account of small-pox, with 3 deaths. Small-pox is usually a very fatal disease among natives of India, but that vaccination and revaccination have conferred upon the native troops a remarkable protection is shown by the fact that out of the 695 cases that have occurred among them during the last 10 years only 30 proved fatal, giving a case mortality of 4·3 per cent. Malaria accounted for over 39 per cent. of the total number of admissions from all causes, October and November being the months of greatest prevalence. There were 9 cases of kala-azar reported during the year, 4 of which proved fatal The stations affected were Dehra Dun, Kila Drosh, and Abbottabad. The diagnosis was confirmed by finding the Leishman-Donovan parasites in blood obtained by splenic or hepatic puncture, or in smears from the spleen after death. The medical officer of one of the regiments at Dehra Dun considered that the prevalence of the disease in that station is increasing. Typhus fever caused 4 admissions and 2 deaths.

A noteworthy increase has been recorded in the number of cases diagnosed as enteric fever in the native army during recent years. It is coincident with a yearly decline in the number of cases returned under the heading of remittent fever. The probability that altered diagnosis rather than a real extension of prevalence is the cause of the recorded increase is supported by the results of a detailed examination of the statistics. In 1908 350 admissions, with 73 deaths, from enteric fever occurred. The source of infection was not definitely ascertained in any case that occurred among native troops during the year, and this is not surprising when we know that the great majority were diagnosed on admission to hospital as malaria and that usually 10 days or a fortnight elapsed before the diagnosis of enteric fever was made by the ineffectiveness of quinine in treatment and the results of the Widal test. The Sanitary Commissioner thinks that it will probably be some years before what may be called the normal incidence of enteric fever among native troops is accurately reported, and that until then it would be wrong to consider that the real prevalence of the disease is increasing among them.

Malta fever caused 23 admissions. The largest number of cases in any regiment was 7 in the 32nd Sikh Pioneers stationed at Ambala. All the patients in this regiment gave a history of having drunk goats' milk, but although many goats in an adjacent village were examined none were found to be infected. An order was issued prohibiting the bringing of female goats to the lines, and it is said that after the issue of this order only one case—a doubtful one—of Malta fever occurred. Coincident with the fall of plague among the general population of India in 1908 the number of cases among native troops fell from 85 in 1907 to 36, and the number of deaths from 56 to 14. Scurvy caused 191 admissions. The largest number of cases occurred in the 126th Baluch Infantry (18 admissions) at Quetta, 17 of the cases occurring among men of the detachment at Robat, where the only vegetables available were onions, and even these were not obtained during June, and 13 of the cases occurred during July. The 112th Infantry, which had detachments on the Persian Gulf, recorded 14 cases. The admission-rate for tubercle of the lungs rose from 2·5 per 1000 in 1907 to 3·0, and the death-rate from 0·33 to 0·42, the total number of admissions and deaths being 322 and 42 in 1907, compared with 378 and 53 in 1908. Dysentery caused 5019 admissions to hospital and 28 deaths. Venereal diseases caused 1934 admissions, giving a ratio of 15·2 per 1000, as compared with 4801 admissions and a ratio of 69·6 among European troops. There were 13 admissions to hospital for beri-beri and there was no death. Ten of the cases occurred in the 83rd Light Infantry, stationed at Cannanore, the disease being of a mild type and confined to recruits. No case occurred among the civil population of the district, and beyond suggesting that the consumption of bad rice may have been concerned the officer in medical charge of the regiment was unable to account for the outbreak.

The Jails of India.

Poor and belated harvests raised the already high prices of food and high prices led to an increase of crime, and the

number of prisoners admitted into the jails rose from 291,165 in 1907 to 341,831, a total increase equal to 17 per cent. Many of the prisons were continuously overcrowded and a large proportion of the newly-admitted prisoners were in a bad state of health owing to the effects of scarcity of food and malarial infection. It is, however, creditable to those concerned with the administration and management of the jails to record that in spite of these adverse conditions the health of the prisoners remained fairly good. The admission and constantly sick rates were only slightly higher than those of former years. The death-rate was 24·17 per 1000, as compared with 18·51 in 1907. The diseases which caused the highest rates of admission to hospital were: malaria (197·7 per 1000), dysentery (76·9), abscesses, ulcers, and boils (65·2), and diarrhœa (37·6). The diseases which caused the highest death-rates were dysentery (4·67 per 1000), tubercle of lungs (3·76), and pneumonia (3·24). Malarial fevers, although the commonest of the diseases, are seldom the direct cause of death in prison. In 1908 there were 20,039 cases of malarial fever treated in the jail hospitals and only 105 terminated fatally. Assuming that all the recorded deaths were due to malaria only, which the records show was by no means the case, only one attack in 191 cases ended fatally, which proves that even in a year when malaria was peculiarly severe malarial diseases, when efficiently treated—using the term in its fullest sense—are by no means fatal. "It appears from the evidence," says the Sanitary Commissioner, "whatever the value of measures taken against mosquitoes, whether to prevent their breeding or to prevent their biting, that in a very malarious year in prisons the administration of quinine is for the present the remedy upon which reliance must be placed." Judging by the success attained in the Punjab (undertaken under the personal direction of the Inspector-General of Prisons, Lieutenant-Colonel G. F. W. Braide, I.M.S.) and generally elsewhere, when special efforts were made to carry out the administration of quinine in a thorough manner, there is every reason to hope that as the prophylactic use of quinine becomes more widely adopted the decline in the frequency of malarial infections will continue. Dysentery caused no less than 7796 admissions and 473 deaths in 1908, as compared with 6328 admissions, with 240 deaths, in 1907. Of the 473 prisoners who died from dysentery during the year, 253, or nearly 53 per cent., had been less than six months in prison. Tubercle of the lungs caused 951 admissions, with 381 deaths, during the year under review. The opinion is widely held, and evidence has been brought forward to prove, that tuberculous disease, particularly tubercle of the lungs, is increasing in India, especially in the towns. It appears, however, that tubercle of the lungs, although prevalent, is not increasing among prisoners as a body. There were 337 cases of cholera and 170 deaths; all the deaths except 3 occurred in the four northern jails, where the prevalence and severe mortality from the disease are attributed by the Inspector-General to conditions of famine amongst the people. There were 122 cases of small-pox and 15 deaths, 10 cases of plague and 5 deaths, and 113 cases ascribed to enteric fever, of which 36 terminated fatally. In 21 jails two or more cases of enteric fever were recorded, and in all but four of the fatal cases the post-mortem appearances confirmed or supported the clinical diagnosis. In regard to the jails and other matters connected with sanitation, further information will be found in a recent series of articles dealing with various sanitary reports from India.[1]

Vital Statistics of the General Population.

The total population now under registration in India is 226,409,600. The total births registered were 8,554,427, giving a birth-rate of 37·78 per 1000, compared with 37·65 in 1907. The Central Provinces again showed the highest birth-rate—namely, 52·84 per 1000; the lowest birth-rate was recorded in the small province of Coorg, where it was 24·17, the low rate being attributed to exceptional circumstances, amongst them being the small proportion of females in the population. The total deaths registered were 8,653,007, compared with 8,399,623 in 1907 and a five years' mean of 7,680,007. The death-rate was 38·21, or 1·03 per 1000 higher than in 1907 and 4·25 higher than the mean death-rate of the previous five years. In the different provinces the rates ranged from 52·73 per 1000 in the United Provinces to 26·2 in Madras. Owing to the severe epidemic of malarial fever in the autumn the fever death-rates in the United Provinces (41·31), the Punjab (34·66), and Ajmer-Merwara (30·79) were exceptionally high.

Chief Diseases among the General Population.

In 1908 there was a considerable increase in the number of deaths attributed to cholera and small-pox, a small increase in the number under dysentery and diarrhœa, and an increase of nearly a million in the number attributed to fevers. Fortunately, the number of deaths from plague decreased very greatly, but from all causes taken together there were recorded in British territory 253,384 more deaths than in 1907. Cholera caused 591,725 deaths, or a death-rate of 2·61 per 1000 in 1908. Small-pox caused 170,694 deaths (0·75 per 1000). Plague caused 156,480 deaths (0·50 per 1000), compared with 1,315,707 (ratio 5·16) in 1907. Fevers caused no less than 5,424,372 deaths, giving a ratio of 23·96 per 1000, as compared with the more or less constant death-roll of 4,500,000 and the mean death-rate of rather less than 19·5 per 1000.

The wave of epidemic malaria which in the autumn of 1908 swept over certain provinces of India—especially the North-Western Provinces—was one of the chief distinguishing features of the year. A very large proportion of the total mortality from fever among the general population occurs among children and the aged, and in epidemic years they suffer disproportionately, because in such years they have to undergo privations which loosen their feeble hold on life. In the Punjab in 1908 the infantile death-rate from fever was doubled, and the fever death-rates among children between the ages of 1 year and 10 years were more than doubled. Among the general population many know that quinine is a remedy for malarial fever and are eager to get it when they are suffering, but many are prejudiced against it, and probably the majority have never heard of it. The advantages of the drug will have to be brought before all those who live in malarious places and they will have to be educated to use quinine in sufficient quantity at the right time. The best preparations for the use of adults and children will have to be selected, and probably much will depend upon the way in which the drug is dispensed. The correct dose will have to be determined, and the Sanitary Commissioner thinks it would be of advantage to issue the drug in tablets or powders equal to the minimum dose sufficient for prophylactic purposes, with directions that the single dose should be repeated a certain number of times at specified intervals as a cure. It is essential, he thinks, that it should be recognised that the distribution of quinine cannot be made self-supporting, and in view of economy, if for no other reason, very careful inquiries will be necessary regarding the needs of different localities. In many places no quinine is necessary at all; in others it is required only for a short time in certain years; in others it is required every year, but only at a certain season; and in yet others there is need for its continuous use. Although our knowledge of the etiology of malaria and its treatment is fairly extensive, it is still wanting as regards (*a*) the best agency for the distribution of quinine, and (*b*) the causes of disease and death as well as the distribution of the disease in a district. There is reason to hope, however, that a permanent organisation for dealing with these and other matters relating to malaria in India will shortly be established as a result of the recent Malarial Fever Congress that met at Simla.

Vaccination.

The total vaccinations performed during the year were 9,123,262, a decrease compared with the previous year of 46,511. The percentage of success attained in primary vaccinations was 97·47, and in revaccinations 73·44. The total cost of the vaccination department was Rs.15,10,536 (£100,702 8*s.*). The mean cost of each successful case was 2 annas 10 pies (nearly 3*d.*). The more important changes concerning the lymph-supply were the closing of the lymph depôt at Lucknow and the opening of a new depôt at Belgaum, whence preserved lymph will be distributed throughout the Bombay Presidency, including Scind, and the introduction of payment for all vaccine lymph issued by the Punjab depôt, to prevent undue waste by demands in excess of requirements.

General Remarks.

Under the above heading of the Sanitary Commissioner's report an account is given of the Red Sea pilgrim traffic and the sanitary measures undertaken to prevent infective diseases

[1] THE LANCET, May 7th (p. 1289), 14th (p. 1369), and 21st (p. 1434), 1910.

being imported into India. Some interesting remarks on the subject of cholera carriers are made with reference to the occurrence of some cases of cholera amongst the pilgrims. The water-supply of the ships carrying the pilgrims was examined bacteriologically and found pure. The diagnosis of cholera in those attacked was established bacteriologically and the problem was, Where did they become infected? Dr. Delpino, the Director of the Quarantine Station at Camaran, believed that the germs of cholera were brought from India in the intestines of the pilgrims themselves, and he attributed the outbreak to a *microbisme latent*. As far back as 1893 it was pointed out by Günther, Rumpel, and Koch that in times of cholera epidemics a considerable proportion of the people exposed to infection carry the cholera vibrios in their intestinal system without manifesting any sign of the disease. Such carriers are temporarily or permanently immune, and it is a generally accepted belief that when the germs carried by them reach a susceptible host they give rise to cholera, which then spreads from the second host in the ordinary way. Dr. Delpino appears to be of the opinion that the vibrios carried by the Indian pilgrims were not virulent, and that for some reason they became virulent at Camaran and caused attacks of cholera in the carriers themselves. Apart from the circumstances of the cases amongst the pilgrims of one of the ships, he was supported in his belief by the discovery of true cholera vibrios in the stools of two pilgrims from another of the ships, who were in hospital on account of intestinal catarrh and dysentery respectively, and in the stools of a pilgrim from the ship on which the cholera cases occurred, who was in hospital suffering from slight catarrhal dysentery. None of these three pilgrims showed any sign of cholera. It is true that cholera vibrios were not found in the stools of those attacked before their attack, but such a discovery has been made elsewhere. Professor W. Kolle has found cholera vibrios in the apparently normal dejections of two members of a family in which a case of cholera had occurred. These two carriers were removed to a hospital where infection was out of the question, and several days afterwards they developed a fairly severe and a slight attack of cholera respectively. It would appear that cholera carriers range between two extreme conditions: those whose escape is due to immunity owing to an idiosyncrasy that protects them against virulent vibrios, and those who, although susceptible, escape because the vibrios harboured by them are not virulent. The first class are a danger to the community in which they live so long as they continue to excrete virulent vibrios; the second class do not become dangerous until some cause, specific or otherwise, confers virulency on the vibrios they are carrying.

The Sanitary Commissioner next reviews the work done at the different Government laboratories in India, which include the Central Research Institute at Kasauli, the Bombay Bacteriological Laboratory, the King Institute of Preventive Medicine, Madras, and the Pasteur Institutes at Kasauli and Coonoor. At all of these institutions good work has been done, and the Sanitary Commissioner is to be congratulated on the hardworking staff of officers over whom he presides. Reference is finally made to the origin, scope, and line of scientific investigations of the Imperial Malaria Conference held at Simla in October, 1909, and to the recent additions to the scientific memoirs published by the Sanitary Commissioner with the Government of India.

PUBLIC HEALTH PROGRESS IN THE PHILIPPINES.

MOST of our readers are well acquainted with the great improvement in public health which has followed the efforts of the medical officers of the United States Government in Cuba and in the Panama Canal Zone of late years mainly by the use of the most modern methods known to science for preventing the occurrence of tropical and other diseases. Public attention has not been directed in a like degree to the similar success which has followed the use of the same methods in America's Asiatic dependency, the Philippine Islands. For this reason the report of the Bureau of Health for the Philippines by Dr. Victor G. Heiser, director of health, is of more than usual interest, and fits well with the delivery of Mr. Roosevelt's Romanes Lecture (see p. 1629).

Since the American occupation of the islands no effort has been spared to improve the conditions under which the population live, and this has been done in spite of passive resistance due to the idleness, apathy, and indifference of many of the inhabitants. One marked result already obtained has been the reduction of the annual mortality rate among the employees of the Government to the low figure of 8·62 per 1000. It is generally anticipated that if all the rules and regulations made by the Health Bureau could be enforced among the general population there would be a similar reduction in their death-rate. As was natural, the evidences of progress are more apparent in Manila, the capital of the islands, than in the provinces. This city, which has an estimated population of 223,542, has been recently provided with a new public water-supply, conveyed by gravitation from an uninhabited gathering ground, yielding 100 gallons per day to every man, woman, and child in the city, and estimated at a cost of over $3,000,000, practically to insure the inhabitants against any serious outbreak of cholera or other water-borne disease. A new sewage scheme has also been carried out, placing Manila, as Dr. Heiser says, in the front rank of oriental cities as regards sewage disposal. Aided by public sentiment, which had latterly been stirred by the reports of the Bureau of Health, much progress has been made in the direction of town planning in the suburbs and in the improvement of the housing accommodation of the poorer classes. No fewer than 3000 of these persons have been recently removed from filthy and congested areas in which there existed no streets or surface drains, where the houses were so closely huddled together that no garbage cart could come near, and where the inhabitants were in the habit of deliberately tossing their excrement out of the windows rather than take the trouble to walk to the public latrine provided for their use. These people are now transferred to houses erected on a new area carefully planned, with properly laid out streets and surface drains, and provided with public baths, laundry, and latrines, as well as having water hydrants placed at proper intervals. Similar improvements, though on a smaller scale, have been carried out in some of the provincial towns, where some 80 artesian wells have recently been sunk. Already the measures prescribed against leprosy have borne fruit, and there has been a diminution in the amount of the disease. It is worthy of mention in this connexion that Mr. Moses T. Clegg, of the Philippine Bureau of Science, has discovered what has long been sought for—namely, a method of cultivating the bacillus of leprosy in artificial media. This discovery is said by Dr. Heiser to give hope that a serum or vaccine will now be obtainable for the treatment of this loathsome disease. An active campaign has also been carried out against ankylostomiasis, or, as it is termed by the American authorities, "hookworm disease," and already many thousands of persons have been relieved of their parasites. Although not far short of 1000 deaths were attributed to beri-beri, yet in the institutions controlled by the Bureau the disease has practically disappeared, through the reduction of the rice in the ration and substituting for it more varied articles to the diet. Amœbic dysentery still retains the first place in the Philippines as the white man's worst enemy. More permanent disability is caused by it, more time is lost through it, and more persons are compelled to leave the islands from this cause than from all the other tropical diseases combined. And yet Dr. Heiser says the ailment is almost unknown among those who use the simple precautions of washing their hands immediately before eating, who only drink water that has been boiled, and who do not eat in a raw state certain low-growing vegetables.

Though much has been done to improve the public health much remains yet to be done. The course which the Bureau of Health proposes to maintain is sketched out at the conclusion of the report. Attempts will continue to be made to improve general sanitary conditions, especially by providing improved water supplies; by enforcing vaccination—1,817,872 persons were vaccinated in the fiscal year; by isolating lepers; by eliminating intestinal parasites which infest the majority of the Philippino population; by systematic warfare against tubercle bacilli, funds for an antituberculosis crusade having now been secured; by eradication of malarial mosquitoes; and by securing better hygiene for infants, for which purpose a grant of money has been made to the Bureau by Government, so that now aid can be given to those societies which have for their object the protection of infant life. In addition to all this work in the prevention of disease and

the dealing with epidemics of cholera and small-pox during the past year, the Bureau of Health is charged with the supervision of the sanitation of prisons, with the management of the newly erected general hospital in Manila and the free dispensaries in that city for the cure of disease, and under it medical and surgical relief has been furnished during the year to many thousands of persons. The Bureau is also largely concerned in the administration of the public charities of the capital.

The health officers in the Philippines are the district medical officers of health, and some of the same difficulties which have been recognised in this country have arisen as regards their tenure of office. Progress is hindered in some measure by the apathy and indifference of many of the municipalities throughout the islands. Each municipality possesses a health officer, but even when this official tries his best to spur his council into action the members often prefer to waste valuable time in factional disputes or in futile and protracted discussions on such a subject, for example, as the comparative value of Guava-water or carbolic acid as an efficient disinfectant. It is not easy for a health officer, when he conscientiously performs his duty, to avoid giving offence to one or other faction in his council. To punish him it is a favourite procedure to reduce his salary to the lowest limit. Dr. Heiser asserts that so long as a health officer is at the mercy of one or another of the factions in his council, an entirely impartial discharge of his important duties cannot be expected of him. To remedy this Dr. Heiser proposes that the scheme recently adopted in Cuba should be put in force in the Philippines—viz., each municipality to have a health officer, or acting health officer, appointed by the director of health, and paid from the Insular Treasury, the Insular Government being reimbursed by the municipality the amount of salary paid. If the municipality is too small or too poor to pay a sufficient salary by itself to attract a competent officer several municipalities should be combined compulsorily to form a district to be served by a joint health officer. Similar arrangements are suggested for the appointment of sanitary inspectors. Another very important point is emphasised by Dr. Heiser; all the locomotion expenses of these health officers and sanitary inspectors should, in his opinion, be defrayed by the municipalities. In this way prompt visits in emergencies would be more likely to be paid by the officials, and systematic inspection of outlying areas would be more surely secured. Frequent visits are often necessary in the public interests, but it is a great call upon an official with a moderate salary in a wide district to expect him to pay these frequent visits when he has to lay out considerable sums in travelling expenses from his own pocket.

In conclusion, we may add that this most interesting and comprehensive report is illustrated by a number of photographic reproductions which give the reader a very good idea of the conditions described in the text, more especially as regards the hovels and the insanitary areas to which reference is made.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 9th, 1832.

APPLICATION OF

GASTRIC JUICE

TO THE PURPOSES OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The observations I am about submitting to your consideration, first originated by my perusing in your Journal a short time since some very trite remarks on the gastric juice, and the application of the gastric juice of animals in the cure of certain diseases of the stomach, such diseases being supposed to owe their origin to a scarcity of the necessary juice for the usual digestive process. I well remember your correspondent cited some very satisfactory results from the employment of the animal juice.

After I had attentively considered the subject, the thought struck me, that as gastric juice was a fluid, which it was difficult if not impossible to procure, some other preparation may in its stead be instituted; but as it was an animal production, I was on the point of giving up the subject, not being possessed of chemical apparatus sufficient to moot the matter to the base, when happening to dine that day with some professional friends, the subject of the formation of cheese was brought on the carpet, as well as on the table; one idea led to another, and after returning to my study, I briefly recapitulated the substance of our conversation. One observation of my friend at the time particularly struck me; he stated, that "a liquid called rennet (which was formed from what are commonly called Irish vells, such articles being nothing more or less than the stomachs of calves salted) was dropt into milk, which immediately from its acidity produced a decomposition of its parts; the thicker was precipitated, commonly called curds, and a thin serous fluid formed on its surface denominated whey; he further stated, that it was a generally-received thing among men of agricultural research, that the gastric juice of the vell which produced the decomposition." Now, Sir, my hypothesis is of a very simple nature; we all know albumen is decomposed by acids, therefore what can produce the decomposition in milk if there be not an acid present? And what can that acid be, but the gastric juice contained within rennet? We all know that gastric juice is acetous in a high degree, which proves at once that it can be no other than the real gastric juice of the calf which constitutes the active effect to be found in rennet. I have not, Sir, since forming the above conclusion had a case under care in which I could employ the rennet, but I do not hesitate a moment in giving my opinion, that in those diseases of the stomach in which there is a deficiency of the gastric juice (which frequently occurs in dyspepsia), the employment of rennet would be of material advantage; at least I speak from supposition. Amongst the ranks of the profession, if any gentleman be found who will give his especial attention to this subject, he will merit the thanks of the lovers of science I am well assured. And now, Sir, I must apologise for having so long trespassed on your favour; and having introduced this subject to the attention of the profession, I beg leave to bequeath it to abler and more efficient hands; and believe me, Sir, to remain your obliged humble servant,

Hants, May 16th, 1832. G. J. P.

BRITISH MEDICAL BENEVOLENT FUND.

AT the May meeting of the committee 14 cases were considered and grants amounting to £131 made to 12 of the applicants. Appended is an abstract of the cases relieved:—

M.R.C.S., aged 71 years. Quite incapacitated by senile gangrene and dependent on children who can ill afford to help. Voted £10.

Widow, aged 40 years, of M.B., C.M. Edin. Only income £15 a year interest on insurance money. Four children, aged 11 years to 3 years. Voted £10.

Widow, aged 48 years, of M.R.C.S. Has maintained herself by keeping a boarding-house since husband's death, but has had a bad season and asks for a little help towards the education of her children. Voted £10.

Widow, aged 41 years, of M.R.C.S. Husband died a few weeks ago and so far has been unable to sell the death vacancy. Income £14 per annum. No children. Voted £5.

Widow, aged 54 years, of L.R.C P. Edin. Quite unprovided for at recent death of husband; children unable to help and one still at school. Voted £10.

Daughter, aged 47 years, of late M.D. Aberdeen. Has supported herself by assisting in a boarding house kept by her mother recently deceased, and asks for help towards unavoidable expenses of the illness. Voted £10.

L.R.C.P., L.R.C.S. Edin., aged 50 years. Lost his sight a few years ago and is dependent on his wife who lets lodgings. Four children aged 15 to 10. Relieved twice, £36. Voted £18.

Daughter, aged 65 years, of late M.R.C.S., L.S.A. Acted as housekeeper for a brother until his death in 1890 and then qualified as a maternity nurse, but now finds extreme difficulty in obtaining engagements. Relieved once, £12. Voted £12.

Daughter, aged 50 years, of late M.R.C.S., L.S.A. Suffers from chronic glaucoma and dependent on slight help from friends and occasional earnings as a nurse. Relieved twice, £15. Voted £10.

Daughter, aged 59 years, of late M.R.C.S., L.S.A. Earns about 5s. a week by needlework and receives the same amount from friends. Relieved three times, £42. Voted £12.

Daughter, aged 67 years, of late M.D. Lond. Maintained herself as a governess for more than 40 years, but is now quite incapable of work. Relieved twice, £24. Voted £12.

Widow, aged 70 years, of M.D. Edin. Dependent on a small weekly allowance given locally and earns a few shillings occasionally by knitting. Children unable to help. Relieved six times, £69. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 8778 births and 3836 deaths were registered during the week ending June 4th. The annual rate of mortality in these towns, which had been equal to 12·4 and 12·7, per 1000 in the two preceding weeks, declined to 11·8 in the week under notice, and was considerably lower than in any previous week of this year. During the first nine weeks of the current quarter the annual death-rate in these towns averaged only 13·4 per 1000, and in London during the same period it was so low as 13·0 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 3·1 in King's Norton, 3·3 in Walthamstow, and 4·3 in Handsworth, all being suburban districts; the rates in the other large towns ranged upwards, however, to 17·0 in Bootle, 18·2 in Liverpool, 18·4 in Merthyr Tydfil, and 19·9 in Oldham. In London the recorded death-rate did not exceed 11·6 per 1000. The 3836 deaths registered last week in the 77 towns showed a further decline of 306 from the low numbers in recent weeks, and included 369 which were referred to the principal epidemic diseases, against 400 and 424 in the two preceding weeks; of these 369 deaths, 141 resulted from measles, 122 from whooping-cough, 46 from diarrhœa, 27 from diphtheria, 21 from scarlet fever, 10 from enteric fever, and 2 from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·1 per 1000, against 1·2 and 1·3 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Sunderland, Walthamstow, Brighton, Derby, and in 16 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·9 in Smethwick and in Stockton-on-Tees, 3·8 in Burton-on-Trent, and 3·9 in Merthyr Tydfil. The fatal cases of measles in the 77 towns, which had been 141 and 157 in the two preceding weeks, declined again last week to 141, but caused annual rates equal to 1·9 in Blackburn, 2·8 in Burton-on-Trent, and 3·9 in Merthyr Tydfil. The 122 deaths from whooping-cough showed a decline of 37 from the number in the previous week; the highest annual rates from this disease last week were 1·4 in Smethwick and in Wallasey, and 1·7 in Huddersfield. The 46 deaths attributed to diarrhœa were fewer by three than those in the previous week. The fatal cases of diphtheria, which had been 37 and 20 in the two previous weeks, were 27 last week, of which 6 occurred in London and its suburban districts, 2 in Manchester and Salford, 2 in Liverpool, and 2 in Hull. Of the 21 deaths from scarlet fever, 4 were returned in Birmingham and 2 in Coventry. Only 10 deaths in the 77 towns were last week referred to enteric fever, including 2 in Portsmouth. Of the 2 fatal cases of small-pox, 1 each occurred in South Shields and Cardiff. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 33 preceding weeks from 2810 to 1445, had increased to 1461 on Saturday last; 203 new cases of this disease were admitted to these hospitals during last week, against 190 and 174 in the two preceding weeks. Of the 1087 deaths registered in London during last week 174 were referred to pneumonia and other diseases of the respiratory system, and were 17 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 31, or 0·8 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Salford, and in 51 smaller towns; the 31 uncertified causes of death in the 77 towns last week included 5 in Liverpool, 4 in Sunderland, 3 in Gateshead, and 2 each in Reading, Sheffield, and Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 954 births and 517 deaths were registered during the week ending June 4th. The annual rate of mortality in these towns, which had been equal to 15·5 and 14·0 per 1000 in the two preceding weeks, rose again to 14·3 in the week under notice. During the first nine weeks of the current quarter the death-rate in these towns averaged 16·1 per 1000, and exceeded by 2·7 the mean rate during the same period in the 77 large English towns. The annual death-rates last week in these eight Scotch towns ranged from 9·6 and 11·4 in Aberdeen and Edinburgh, to 15·6 in Greenock and 20·2 in Dundee. The 517 deaths from all causes in the eight towns during last week showed an increase of 11 upon the number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 80, 63, and 62 in the three preceding weeks. These 50 deaths were equal to an annual rate of 1·4 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·1 per 1000. These 50 deaths in the Scotch towns last week included 20 from measles, 15 from diarrhœa, 7 from whooping-cough, 3 from scarlet fever, 3 from "fever," and 2 from diphtheria, but not one from small-pox. The fatal cases of measles in the eight towns, which had declined from 52 to 33 in the four preceding weeks, further fell last week to 20, of which 9 occurred in Dundee, 7 in Paisley, and 2 in Edinburgh. The 15 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 7 in Glasgow. Of the 7 deaths from whooping-cough, an increase of 2 upon the number in the previous week, 4 were returned in Glasgow and 2 in Dundee. Two of the 3 fatal cases of scarlet fever, and both the deaths from diphtheria, occurred in Glasgow. Of the 3 deaths referred to "fever," 2 were returned in Glasgow and 1 in Leith; 1 (in Leith) was certified as typhus, and 1 each as enteric and cerebro-spinal meningitis in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had been 98 and 80 in the two preceding weeks, were 82 in the week under notice, and were 11 below the number returned in the corresponding week of last year. The causes of 19, or 3·7 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 704 births and 397 deaths were registered during the week ending June 4th. The mean annual rate of mortality in these towns, which had been equal to 19·5 and 21·1 per 1000 in the two preceding weeks, declined to 18·0 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these Irish towns averaged 21·2 per 1000, whereas the mean rate during the same period did not exceed 13·4 in the 77 largest English towns and 16·1 in the eight principal Scotch towns. The annual death-rate during last week was equal to 15·7 in Dublin, 22·1 in Belfast, 16·4 in Cork, 13·2 in Londonderry, 17·8 in Limerick, and 31·2 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 14·2 per 1000. The 397 deaths from all causes in the 22 town districts last week showed a decline of 70 from the number returned in the previous week, and included 58 which were referred to the principal epidemic diseases, against 59 and 50 in the two preceding weeks; these 58 deaths were equal to an annual rate of 2·6 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·1 per 1000, while in the eight Scotch towns it was equal to 1·4. The 58 deaths from these diseases in the Irish towns last week included 39 from measles, 11 from whooping-cough, 5 from diarrhœa, and 3 from scarlet fever, but not one from diphtheria, "fever," or small-pox. The fatal cases of measles in the 22 town districts, which had been 45 and 33 in the two previous weeks, rose again to 39 last week, of which 38 occurred in Belfast. The 11 deaths from whooping-cough also showed an increase, and included 7 in Belfast and 2 in Dublin. Three of the 5 deaths attributed to diarrhœa were returned in Belfast; and of the 3 fatal cases of scarlet fever, 2 occurred in Dublin and 1 in Belfast. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 84 and 90 in the two preceding weeks, declined to 75 in the week under notice. The causes of 14, or 3·5 per cent., of the deaths registered in the Irish towns last week

were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent., while in the eight principal Scotch towns it was equal to 3·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Staff-Surgeon Ernest Stewart Reid has been placed on the Retired List (dated May 26th, 1910).

The following appointments are notified:—Fleet-Surgeon: W. W. Pryn to the *President*, additional, for three months' hospital course. Staff-Surgeons: H. C. Whiteside to the *Circe*, temporarily; J. G. Peebles to the *Natal;* and J. G. Watt and N. J. Roche to the *King Alfred*, additional. Surgeons: C. G. Sprague to the *Vivid*, additional, for disposal; W. P. Yetts to Chatham Marines; J. J. H. Rooney to Gibraltar Hospital; O. M. W. Hearn to the *Victory*, additional, lent to Physical Training School, and to the *Victory*, additional, for Physical Training School; S. H. Vickery to the *Vindictive;* and J. L. Barford to the *Impregnable*.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Charles H. Burtchaell, R.A.M.C., to be Assistant Director-General, vice Lieutenant-Colonel J. M. Irwin, whose tenure of that appointment has expired (dated June 1st, 1910).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels retire on retired pay (dated June 4th, 1910): James H. Curtis and William B. Day.

Lieutenant-Colonel G. G. Adams, from Cosham, on arrival in India, has been appointed to command the station hospital at Hyderabad, Sind. Major E. T. Inkson, V.C., has been transferred from St. Thomas's Mount, Madras, to the station hospital at Bangalore. Major C. J. O'Gorman, D.S.O., from Scarborough, has on arrival in India been posted to Nowshera for duty. Captain M. Sinclair, from Sialkot, has been posted to the Irish Command and appointed to Cork District. Captain W. J. Waters, from Devonport, has been transferred to Crownhill. Captain H. A. Davidson, from Queenstown, has been posted to Buttevant. Captain R. N. Woodley has taken up duty at Bulford Camp, Salisbury Plain, from Cahir. Captain A. J. Hill, lately commanding the station hospital at Jutogh, has, on arrival home, tour-expired, been appointed to the Eastern Command. Captain P. G. Hyde has been transferred from Queenstown to Dublin District. Captain A. R. C. Parsons has arrived home on leave from West Africa. Captain A. M. MacLaughlin has been posted to the London District. Lieutenant F. J. Stuart, from Chatham, on arrival in India, has been posted to the station hospital at Lucknow. Lieutenant J. B. Hanafin, from Cork, has joined at Rawalpindi for a course of sanitation.

INDIAN MEDICAL SERVICE.

Colonel D. ffrench-Mullen, Deputy Principal Medical Officer, His Majesty's Forces in India, has arrived home on eight months' combined leave. Colonel C. J. Bamber, Sanitary Commissioner of the Punjab, has been appointed to officiate as Inspector-General of Civil Hospitals in the Punjab, vice the Hon. Colonel T. E. L. Bate, C.I.E., on leave. The services of Major S. A. Harris, Deputy Sanitary Commissioner, First Circle, United Provinces, have been replaced at the disposal of the Government of India, Home Department. Major S. Hunt has been granted seven months' leave combined with furlough. Major P. Dee and Major J. Mulvany have arrived home on leave. Major T. H. Symons, Madras, has had his leave extended. The services of Captain D. C. V. Fitzgerald, Officiating Civil Surgeon, Sibsagar, Eastern Bengal, have been replaced at the disposal of the Government of India. The Lieutenant-Governor of the Punjab has appointed Captain N. H. Hume, Officiating Superintendent of the District and Female Jails at Lahore, to act as Civil Surgeon and Superintendent of the Central Jail at Montgomery, Punjab, during the absence on leave of Captain J. E. Clements. Captain W. McH. Pearson has arrived home on leave. Captain A. Cameron has been appointed for special duty in connexion with the prevention of plague in the Punjab.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Lancashire Field Ambulance: Lieutenant-Colonel John J. K. Fairclough resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated May 1st, 1910).

Highland Mounted Brigade Field Ambulance: Lieutenant-Colonel John Macdonald reverts at his own request to the rank of Major (dated April 5th, 1910). Major John Macdonald resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated April 6th, 1910).

For attachment to Units other than Medical Units.—John Tait to be Lieutenant (dated June 30th, 1909). William John Harrison to be Lieutenant (dated April 29th, 1910). Cuthbert Delaval Shafto Agassiz to be Lieutenant (dated April 30th, 1910). Francis Dawson Blandy to be Lieutenant (dated May 3rd, 1910).

Attached to Units other than Medical Units.—Captain Charles W. Crawshaw resigns his commission (dated April 30th, 1910).

THE BRITISH RED CROSS SOCIETY.

Nearly 200 women and 300 men, employees of the Prudential Insurance Company, Limited, Holborn, W.C., have signified their intention of joining first-aid classes and subsequently detachments of the City of London Branch of the British Red Cross Society.

We understand that efforts are being made to form a detachment of Scottish women to be attached to the London Scottish Regiment of Territorials.

Correspondence.

"Audi alteram partem."

THE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

To the Editor of THE LANCET.

SIR,—On behalf of the Council of the Association of Medical Officers of Health we ask your earnest attention to the following statement:—

(i.) On July 22nd next, and following days, the Representative Meeting of the British Medical Association will assemble in London.

(ii.) As a result of action taken by our Association, the representatives of the Richmond, Rochdale, and Salford Divisions of the British Medical Association will, at this meeting, move *the rescission of Minute 234* (1909).

It is of the utmost importance, therefore, that no effort should be spared to place the true facts of our case before the various divisions in order that the Richmond, Rochdale, and Salford representatives be sufficiently supported.

(iii.) The representative of the Salford Division will move—

> "That in every form of public medical service the system of part-time appointments of medical practitioners should be maintained as far as such appointments can be made consistently with the requirements of the services, and that all public medical officers should be protected in carrying out their duties, should be secured from capricious dismissal or reduction of salary, and should be allowed to participate in any superannuation scheme approved by a Local Government Board."

We agree most cordially with the spirit of this motion, and trust you will do all in your power to ensure its adoption, in the interests, not only of part-time medical officers of health, but of Poor-law medical officers, public vaccinators, and others whose appointments may be imperilled or threatened.

(iv.) The Public Health Committee of the Central Council of the British Medical Association, although originally instructed to delete from the Public Health Officers Bill all reference to security of tenure for

part-time medical officers of health, have now so far modified their position as to suggest that the Local Government Board "may" insist upon the same terms of appointment for part-time medical officers of health (in cases where the Board shall deem it desirable) as are proposed for whole-time officers.

Our Council has unanimously resolved that to distinguish, in respect of tenure, between part-time and whole-time medical officers of health is, in the public interest, undesirable; and has decided to oppose in Parliament any Bill which seeks to introduce such distinction.

(v.) Mr. F. E. Fremantle, F.R.C.P., F.R.C.S., county medical officer of health for Hertfordshire, proposes to read, before the Section of State Medicine, at the meeting of the British Medical Association in July, a paper on "The Work of the Part-time Medical Officer of Health," and to move:—

"That part-time medical officers of health have in the past played a most important part in the advancement of public health; that their special clinical experience, their personal intimacy with patients, and their comparative financial independence give them exceptional opportunities for securing acceptance of their views; and that the interests of public health will be best promoted by securing a better education of all medical men in public health work than in making any rule to separate preventive from curative work in the activities of the medical profession."

It is particularly hoped that plenary support will be given to Mr. Fremantle, both by attendance and in debate.

(vi.) It has been arranged to hold a general meeting of our Association, in connexion with that of the British Medical Association, on July 29th. The exact time and place will be announced later, but a full attendance is looked for, as an opportunity will arise for discussing the decision which will, by then, have been arrived at by the Representative Meeting in respect of Minute 234 and the consequent notices of motion.

(vii.) A dinner will be held at the Holborn Restaurant on Friday, July 29th, at 7.30 P.M. Tickets, 5*s.* 6*d.* each, exclusive of wine. The presence of official guests of influence and distinction is expected, and the Council will be much assisted if gentlemen who propose to attend (with or without bringing personal guests) will kindly notify their intention by card as early as possible in June to the hon. secretary, Dr. Belilios, Queen's-road, Wimbledon, S.W.

We are, Sir, yours faithfully,

F. G. CROOKSHANK, Chairman.
D. A. BELILIOS, Hon. Secretary.
E. G. GIBBS-SMITH, Hon. Treasurer.
} The Association of Medical Officers of Health.

London, S.W., June 1st, 1910.

THE OPERATION FOR CLEFT PALATE.

To the Editor of THE LANCET.

SIR,—The letters of Mr. T. H. Kellock and Mr. R. W. Murray in the recent issues of THE LANCET on this subject are of great interest. I quite agree with Mr. Murray that it would be very instructive if those surgeons who advocate the early flap operation would bring forward their patients and show us the results of the operation. But I am afraid we shall have to wait, for a short time ago, with a view to investigating the after results of the early flap operation and to compare them with those of operations performed at a later period of life, I requested permission to examine the records of one of the children's hospitals in London, where I understand this operation is frequently performed. It would almost appear as if the results were not so brilliant as we have been led to believe. Otherwise it is difficult to understand the reticence of the advocates of the early flap operation to bring forward their cases or to allow an impartial, and, I hope, a scientific, investigation to take place. It is possible, however, that we may have a full report from this hospital, as I was told "it seems likely that some of the staff will utilise the same material."

At the Leicester meeting of the British Medical Association in 1905 Mr. James Berry read a paper on 67 consecutive cases he had operated on by the older method at ages varying from 2 years to 16 years, and he showed a number of his patients, thereby allowing everyone to judge for himself what his results were. Surely it ought not to be impossible in London to get together a number of cases of the early flap operation and enable everyone to see how badly or how well the patient speaks. A comparison of the two sets of cases would also be possible. In the early part of this year I saw two children of 10 years who had been operated on in London at three years of age by the flap method, and certainly the results, neither as regards speech nor the closure of the cleft, encouraged me to depart from the older method of operating. Possibly these are two more exceptionally bad examples. The mere closure of the cleft is not the most important thing: to give the patient a freely moveable well-formed soft palate is what should be always aimed at, and how is a flap composed of mucous membrane only to do this? I am, Sir, yours faithfully,

Harley-street, W., June 6th, 1910. T. P. LEGG.

IS APPENDICITIS CONTAGIOUS?

To the Editor of THE LANCET.

SIR,—In the *Times* of a few days ago appeared a short paragraph stating that the medical officer of health for the Farnham rural district had reported to the council that appendicitis had increased in his district to an alarming extent. The increase of the disease is only too well known, and most practitioners of medicine must be fully alive to the fact, but, so far as I know, the statement alluded to above is the first indication that the disease may so decidedly affect a limited district or locality. We all recognise the fact that there is, and has been for some ten years, a very marked increase in the prevalence of the disease, but I question whether it is as generally recognised that the type of the disease has altered and that the specific virulence has also altered and increased.

In a clinical lecture on appendicitis given by me at the West London Hospital in February, 1897, I spoke of those attacks of sudden acute onset usually associated with an appendix rapidly becoming gangrenous, and I remarked that, based on an experience of some 20 years of active hospital work, such cases were happily comparatively rare, and that but few had come under my personal care. An old house physician of about that period stated that during his six months of office, as far as he could remember, no case of the character had been under his care. Gradually a change of type supervened, and within a few years of the date of making the statement I have just quoted, instead of seeing case after case of appendicitis running a simple benign course and speedily recovering under medical treatment, we have been called upon to deal with a vast number in which a rapidly sloughing or gangrenous appendix necessitated immediate operation, and it would not be an exaggeration to say that whereas in the "seventies" and "eighties" those cases were only met with comparatively rarely, they are now of almost daily occurrence.

Many reasons have been assigned from time to time as causes for the remarkable increase of the disease. It is not my intention to discuss them; one and all they appear to me to be insufficient to explain as a common cause an illness appearing under such a multitude of varying conditions. But if we recognise that with a marked increase of the disease there has also been a change of type as regards its virulence, and that within the memory of many now living a disease which formerly ran a fairly constant benign course under a simple medical treatment has become not only far more frequent but has also assumed a much more serious form, it seems to me to afford a hypothesis which may give a clue to the true underlying cause of the disease, and justifies the assumption that in appendicitis we are dealing with the local effect of a pernicious organism, possibly but a virulent variety of the bacillus coli communis, the organism affecting a locality or nidus which by its anatomical position produces, when affected by a destructive lesion, such disastrous consequences.

Have we not in the behaviour of another pernicious organism, that of diphtheria, a somewhat analogous course? Fifty years ago it was a comparatively rare disease, and if we take the clinical description as given by the late Sir William Jenner in his classical lecture delivered in 1861, not only presenting different clinical aspects, but of a vastly

more dangerous type; of 58 cases seen by Jenner, 34 proved fatal. Even if we grant to the full the influence of antitoxin we must acknowledge that in the "fifties" and "sixties," and according to Trousseau and other writers at a much earlier date, the specific virulence of the organism was far greater than as seen at the present day. "Tear off the lymph," writes Jenner, "and you will expose a bleeding surface which in a few hours will be re-covered with lymph."

In the early days of practice I saw many such cases, but are they common now? Is it not true that the disease as bacteriologically determined is far more common, far less dangerous to life, and with less pronounced physical characters than in former years? The tough wash-leather membrane upon which so much stress was laid in making a diagnosis has been replaced in a vast number of cases by a soft molecular, pultaceous secretion which frequently cannot by naked eye be differentiated from the simple discharge seen smearing the tonsils in ordinary follicular tonsillitis. I believe clinical knowledge will support the view I hold that in diphtheria we have a disease produced by a pernicious organism, and, moreover, affecting by choice a limited anatomical area—a disease which within memory of many now living, from being of comparative rarity and of great specific virulence, has gradually become vastly more common and of a far less severe type. Moreover, with the diminished virulence there is in a large proportion of cases a marked difference in the physical signs which were considered as being pathognomonic of the disease.

Appendicitis has without a shadow of doubt become within a few years vastly more common; not only has it become more frequent but it has assumed a far higher degree of intensity or virulence. It appears that there is a tendency for the disease to affect certain families, and many cases are known to occur in the same households. If the disease be due, as I believe it to be, to the effect of microbic influence, the micro-organism affecting the host may under certain conditions be conveyed from individual to individual, and we must regard appendicitis as being contagious.

I am, Sir, yours faithfully,

June 4th, 1910. DONALD W. C. HOOD.

CANCER AND ITS EARLY TREATMENT.

To the Editor of THE LANCET.

SIR,—I believe it is fairly correct to state that on an average one out of ten persons over the age of 35 is destined to die from cancer. It is also true that surgery offers the only possible cure and everything depends upon early treatment. Now, Sir, it seems to me the acme of stupidity to bemoan the fact that most patients only seek treatment when they are beyond hope when we do absolutely nothing to disseminate certain simple information which, did they but possess it, would cause these people to obtain early advice.

We allow the public to associate cancer with pain when we know ourselves that the condition is usually painless in its early and curable stages. We still let women imagine that irregular discharge and hæmorrhage are natural conditions at the time of the climacteric. Obstinate and increasing constipation, occurring for *the first time over the age of 40*, ought to indicate a possibly serious state of affairs. Similarly, rectal hæmorrhage and discharge should not be *thought* to be due to "piles," but the individual affected should know that he ought to make sure about it. Personally, I think all women who believe "the change of life" is taking place should consult their medical man to ascertain if the symptoms are really due to this, and if so they should be seen once in three months until the patient is well over this dangerous time. There are signs and symptoms which, although not necessarily indicating cancer, are so suggestive as to make it absolutely necessary that advice should be obtained without delay, and if a knowledge of these "danger signals" were common property we should, I am convinced, have a very much reduced death-rate.

I would suggest that a carefully thought-out notice containing the necessary information in appropriate language should at regular intervals be published in the lay press. There are two possible objections to this: we might cause the public to become unnecessarily scared, and the required information might be considered too indelicate for publication. To the first objection I would reply that medical men are not unduly nervous about themselves, that it would be easy for a nervous person to get his mind set at rest, and lastly, and above all, that the ill-results of the unnecessary alarm in a few neurotic individuals would be overwhelmingly counterbalanced by the good that would result from the early treatment and hopeful outlook of many victims who would have otherwise been beyond help. To the second objection we might retort that a knowledge of cancer symptoms is not one whit more disagreeable than is the subject matter of the advertisements of quack pills and potions, and it would be *for the benefit of humanity*, whereas the quack advertisements are unpleasant reading, hoodwink the public, and benefit no one except a select number of unscrupulous individuals.

I think everyone will agree that the public ought to know more, but there is likely to be a difference of opinion as to the means to be employed. At any rate, it would be interesting to know what the profession, especially the out-patient surgeons, think of the idea.

I am, Sir, yours faithfully,

Shanklin, Isle of Wight, June 4th, 1910. PERCY GULLY.

MEASLES AND THE POST-OFFICE AUTHORITIES.

To the Editor of THE LANCET.

SIR,—In a letter on this subject which appears in your columns this week Dr. S. R. Collier alludes to our practice at the isolation hospital at Mortlake not quite accurately. We do *not* separate our patients with glass screens, and the reason why our nurses do not convey infection is because we take special care to prevent them doing so.

I am, Sir, yours faithfully,

Mortlake, S.W., June 4th, 1910. F. G. CROOKSHANK.

THE LUNACY FEES AND THE RESIDENT MEDICAL OFFICER.

To the Editor of THE LANCET.

SIR,—An advertisement in your issue of to-day from the Guardians of the Poor of the Parish of St. Giles, Camberwell, for the post of resident medical officer to their Constance-road workhouse, with a salary of £200 per annum, with extras, contains a rider to the effect that lunacy fees in excess of £60 per annum shall be repaid to the board. This appears to be a resort to exploiting the abilities of the medical officer *in posse* for the benefit of the board. I think on inquiry it will be found, if past custom still prevails, that the receipts from that source amount to three or four times the £60 mentioned. Such a condition needs some investigation, so I draw your attention to the matter.

I am, Sir, yours faithfully,

June 4th, 1910. M.B., C.M. EDIN.

THE CONGRESS OF THE ROYAL HUNGARIAN SURGICAL SOCIETY.

(FROM OUR BUDAPEST CORRESPONDENT.)

THE Congress of the Royal Hungarian Surgical Society has been held recently, and the meeting was well attended. The presidential address was delivered by Professor MAKARA, who said that the past year had been rendered notable by the meeting of the Sixteenth International Congress of Medicine, at which members of the Hungarian Surgical Society heard lectures of world-wide interest.

Professor HÜMÉR HÜLTL discussed the question of Early Operation in Intestinal Obstruction, and dealt exhaustively with the causes producing such obstruction. He mentioned the different varieties of ileus, and referred to its symptomatology. Through his personal experiences, and from an exhaustive study of the literature on the subject, he had come to the conclusion that in mechanical obstruction surgical treatment was the only treatment of any value. In some rarer cases, where an accurate diagnosis could not be made, palliative internal treatment might be adopted for a period of not longer than 24 hours. The method of operation

depended on the anatomical conditions, but the best results might be expected from early surgical intervention.

Dr. COLOMAN MARTINY was of opinion that even in doubtful cases of ileus operative interference should be resorted to, since even a few hours' delay might work irreparable mischief. He proved from statistics that the number of cures recorded in the surgical treatment of this condition was increasing.

Cases of ileus were exhibited by Professor HÜLTL, Professor POLYA, Professor TAUFFER, and Professor HERCSEL.

Dr. CHUDOVSKY exhibited two patients. One had suffered from fracture of the vertebral column, the other had had a fibroma growing on the dura mater. Both had entirely recovered after operation.

Dr. GENERSICH exhibited a patient who had been stabbed, the knife perforating the pericardium and thence penetrating into the abdominal cavity through the diaphragm. The patient's wound had completely healed.

Dr. GERGÖ and Dr. BORSZEKY read papers on Serum Therapeutics.

Dr. LANG read a paper on the Use of Hedonal as a General Anæsthetic. He employed this drug in the clinic of Professor Dollinger. Hedonal was administered by intravenous injections and the results of the method were encouraging.

Professor DOLLINGER spoke on the Surgical Treatment of the Neuralgias of the Trigeminal Nerve. He had been an advocate of extirpation of the Gasserian ganglion, but now preferred treatment by means of injections of alcohol. He had performed this operation in 14 cases with the best possible results.

The method of treating fractures received much attention at the Congress. The first address on this subject was delivered by Dr. HOLZWARTH, who emphasised the importance of diagnosis by means of X rays. He said that in Hungary the best results were arrived at by means of the Dollinger method, which consisted of the application of light plaster dressings. He laid stress on the necessity of freeing the broken limb from the weight of the body.

Dr. TANDOR was of the opinion that proper extension was the most important factor in the treatment of fractures.

BRISTOL.

(FROM OUR OWN CORRESPONDENT.)

The University of Bristol Colston Society.

THE accounts relating to the eleventh annual dinner of the Colston Society held in February last have just been published. The sum subscribed during the year amounted to £478 10*s.* 6*d.*, making the total raised by the society since its foundation £5736. Sir Isambard Owen has consented to accept the presidency for next year. The officers of the society are arranging for an interview with the committees of the Dolphin, Anchor, and Grateful Societies (benevolent societies meeting annually on Colston Day) with a view of enlisting their coöperation in the joint establishment of a Colston Chair of Commerce at the University of Bristol.

The Court of the University of Bristol.

The Right Hon. Lewis Fry, presiding over the second court meeting of the University of Bristol, which sat recently, alluded to the death of His Majesty King Edward VII. and to the encouragement he had given to the foundation of the University. He moved that the seal of the University be affixed to two addresses, one to His Majesty King George V. and the other to Her Majesty the Queen-Mother. This resolution was seconded by the Sheriff and carried unanimously. Various appointments were made and ratified and a large number of ordinances were adopted on the recommendation of the Council and Senate.

The University of Bristol and Athletics.

The athletic side of the new University is not being neglected. At a recent meeting of the University Athletic Club several contests with the University of Birmingham were held, completing a series begun at Birmingham. Of the seven events competed for Bristol won three. During the winter Birmingham beat Bristol at Association football and at hockey, the Rugby match ending in a draw.

Bristol Deaf and Dumb Institution.

The final scheme for the administration of the foundation of the Bristol Institution for the Deaf and Dumb has been drawn up. Its provisions will empower the trustees to apply a certain portion of the income for the benefit of deaf and dumb persons living in Bristol and its neighbourhood by payments towards the provision and equipment of classes and lectures; by assisting deaf and dumb persons over 16 years of age who have attended this or any other certified school for the education of the deaf and dumb to continue their education by learning skilled trades; and by the award of exhibitions.

Presentation to Dr. James Fletcher.

Dr. James Fletcher, who has for nine years been superintendent of the City of Bristol Fever Hospital at Ham Green, is leaving to take up similar duties at the Monsall Fever Hospital, Manchester. He was entertained by the staff of the Bristol health department, from whom he received a present of a silver rose-bowl suitably inscribed. The medical officer of health, Dr. D. S. Davies, in making the presentation, spoke of Dr. Fletcher's departure as a real loss to the city as well as a personal loss to his Bristol friends.

St. Mary's Hospital: Dinner for Past Students in Bristol.

On May 26th 18 St. Mary's Hospital men, past and present, resident in the West of England, met to dine at St. Stephen's Restaurant, Bristol. Mr. Herbert W. Page was in the chair, and the present staff was represented by Mr. V. Warren Low and Dr. Reginald Miller. The occasion was a very pleasant one and it is hoped that it may be repeated. Similar dinners have been held by St. Mary's men at Derby and at Leicester.

Medical Golf.

The recently formed Bristol and District Medical Golfing Society have played its first match at Long Ashton against the Association of Bath Medical Practitioners. The Bristol players won by 7 points to 2½.

Dentistry for School Children.

The Education Committee of the Somerset county council has made an arrangement with several dental surgeons in the county whereby their services may be obtained for the school children. The school managers are to give facilities for dentists to attend on children whose teeth have been found defective on medical examination. It is suggested that the expenses shall be met by requiring the parents to pay from 1*s.* to 2*s.* 6*d.* per child, according to the amount of treatment required, and that when the relatives are too poor to pay local charities or private benevolence should be relied upon.

The Exeter Workhouse.

The Association of Poor-law Unions recently suggested that the workhouses of this country should on certain occasions be thrown open to the general public for inspection. The Exeter board of guardians, therefore, recently invited the residents of that city to inspect the workhouse and new infirmary. The Mayor, the Sheriff, and many members of the corporation and clergymen accepted the invitation, and were satisfied with the arrangements made and the accommodation provided.

Pediculosis in Devonshire.

At Paignton on June 3rd the parents of 17 families were summoned by the Devon County Education Committee on account of the irregular attendance of their children at school. The parents neglected to keep the children free from pediculi, although definite instructions had been given with regard to the necessary treatment, and a period of five weeks' absence had been allowed for the carrying out of this treatment. It was stated that 80 per cent. of the girls attending the Paignton school had pediculosis. The magistrates fined each parent 2*s.* 6*d.*—At Brixham on May 27th several fines of 2*s.* 6*d.* were imposed for similar offences, the chairman of the magistrates (Lord Churston) remarking that in the future the relatives would not be let off so easily.

June 7th.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The prizes will be distributed to the students by Sir Alfred Keogh, K.C.B., in the Governors' Hall on Thursday, June 23rd, at 3 P.M.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Benevolent Society.

THE annual meeting of this society was held last week. The President, Sir Thomas Chavasse, moved a resolution expressing sorrow at the death of King Edward VII. and sympathy with His Majesty King George V. and the Royal Family. The report of the directors stated that the invested funds amounted to £16,090. The sum of £150 was invested during the year. During the past year 25 annuitants had received help, the annual value of the grants varying from £36 to £18. The total sum expended on grants and donations was £734. The income during the year was £833 and the expenditure £786, leaving a favourable balance of £47. The total number of benefit members was 391. Attention was drawn to the very large number of practitioners in the neighbourhood who had not joined, and members were urged to interest others in the work of the society. Dr. R. W. Simon was appointed president for the ensuing year; Mr. W. F. Haslam, president-elect; and Dr. A. V. Bernays and Mr. Jordan Lloyd, vice-presidents. The following were re-elected: Mr. F. Marsh and Mr. Haslam, treasurers; Mr. F. Crowder, honorary solicitor; Dr. T. Stacey Wilson, honorary auditor; and Dr. J. E. H. Sawyer, honorary secretary.

Memorial to King Edward VII.

There has been much discussion in the city upon the form which a memorial to his late Majesty should take. The *Birmingham Daily Mail* has inaugurated a fund with the object of establishing a two-fold memorial: (1) a statue to be placed in some prominent place, such as Victoria-square; and (2) the rebuilding of the Children's Hospital, for which funds are urgently required. Probably a King Edward VII. ward will be founded.

Health of Coventry.

Dr. E. H. Snell, in his annual report as medical officer of health of Coventry, says that although the death-rate last year did not quite reach the record established in the two previous years, it was remarkably low, being only 13·7, and the infantile mortality was only 96. He remarks that "it is a reasonable source of gratification that a manufacturing town such as this should attain rates such as these, rates which would not discredit a health resort, and in fact by many of them is not attained." On an estimated population of 93,500 the birth-rate was 27·8, the average for the previous ten years being 28·9. The zymotic death-rate was 1·6. In a return giving deaths from phthisis it is shown that 13 of the persons were machinists, 21 housewives, and 17 of no occupation; only 6 of the 96 fatal cases were found in houses rented at £20 or over. For some years Dr. Snell has had in mind the desirability of instituting a register of all houses in the city recording their sanitary state; the only hindrance hitherto has been the absence of an adequate staff.

June 7th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine.

THE expedition of medical men, of which Professor Sir Rubert Boyce is the head, organised for the purpose of dealing with the outbreak of yellow fever in Sekondi and Freetown, sailed on June 1st from Liverpool in the African Steamship Company's steamer *Dakar*. On first hearing of the outbreak Sir Rubert Boyce offered to place his services immediately at the Earl of Crewe's disposal in order to organise measures for the stamping out of the disease. From the latest reports received from the colonies concerned it appears that 12 cases of yellow fever had occurred, 9 in Sekondi, and 3 in Freetown. Sailing with Sir Rubert Boyce to Sekondi were Mr. R. Mugliston, Dr. D. Duff, Dr. S. Goodbrand, Dr. M. W. Fraser, Dr. D. T. H. Croby, and Dr. G. E. Moffatt. Dr. W. A. Nicholson and Dr. J. U. Wood proceeded by the same steamer to Freetown, Sierra Leone, to assist in combating the outbreak there.—Dr. Wolferstan Thomas, assistant lecturer in the Liverpool School of Tropical Medicine, has been appointed to the directorship of the new laboratories at Manaos, in the State of Amazonas. These new laboratories are supported entirely by the foreign business firms in Manaos. This is the second institute that has chosen a student of the Liverpool School of Tropical Medicine as its director.

Liverpool Stanley Hospital.

On May 26th there was a meeting of the trustees for the purpose of electing an honorary surgeon to the Stanley Hospital, in succession to Mr. Douglas Douglas-Crawford, who was recently appointed honorary surgeon to the Royal Southern Hospital. There were five candidates. Mr. Arthur J. Evans, formerly attached to the chief field hospital in South Africa during the late war, was elected by a large majority. Mr. Evans also distinguished himself at the time of the great Jamaican earthquake, accomplishing invaluable work on the steamship *Port Kingston*.

Tuberculosis Exhibition in Liverpool.

An interesting exhibition will be held in Liverpool from June 15th to the 25th. The undertaking, which will be under the auspices of the Liverpool health committee, is the outcome of the Countess of Aberdeen's crusade against tuberculosis in Ireland. Charts, diagrams, models of healthy bedrooms, illustrations of effective ventilation, &c., will be shown, a number of these appliances being contributed by the Liverpool health department. The exhibition will be held in St. Martin's Hall, which is situated in a densely populated district. The object of the exhibition is to spread the knowledge of the principles of sanitation among the poor. The Lord Mayor has promised to preside at the opening lecture. Admission to the exhibition and the lectures will be free.

The West Derby Guardians and Accommodation for Chronic Aged Invalids.

The West Derby guardians are moving forward on lines recommended by the Poor-law Commissioners. They have accepted a tender for £103,497 for the erection of a hospital at Alderhey, West Derby, for the accommodation of chronic invalids, principally old people. When the new building is completed, 1000 of such cases will be transferred thereto from the Walton Workhouse, and the board's scheme of classification will thereby be greatly advanced.

The Care of Epileptics: Cheshire Guardians' Conference.

Representatives of seven of the 14 unions in Cheshire gathered at a conference in the Wirral guardians' offices at Birkenhead on May 26th to consider the question of making better provision for the classification of feeble-minded and epileptic cases. The chair was taken by Mr. G. Andrew, the chairman of the Stockport guardians, who said that the question which had brought them together was one of the most important that guardians had to deal with. In his own union such cases were not kept in the workhouse; they were boarded out at a cost of 14*s.* a week each. The importance of coöperation in dealing with the problem was urged and of providing homes in a central part or various parts of Cheshire. The value of proper treatment for these cases in special homes was emphasised. The following resolution was agreed to:—

That the representatives of the boards of guardians present at this meeting agree to coöperate in forming separate homes for epileptics, but do not bind their several boards to any future action until agreed upon by the said boards.

The conference was adjourned. The next meeting will take place at Crewe, at a date not yet fixed, and in the meantime the unions of Cheshire will be circularised and informed of what has taken place, and requesting their coöperation.

June 7th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

A Fund to Assist the Daughters of Medical Men.

Miss Cecile James, who died on April 4th last at the age of 81, left estate valued at nearly £13,000. She bequeathed various annuities to certain relatives and gave instructions in her will that on the death of the survivor the residue of her estate should be allowed to accumulate for 20 years, on the expiration of which period a trust should be founded to

be known as the "Job" fund in memory of her father, Job James, who was formerly a medical practitioner in Merthyr Tydvil. She further desired that grants of sums varying from £20 to £40 should be made from time to time from the accumulated fund to the daughters of medical men to enable them to learn to earn their own living or to assist them if in ill-health.

The Medical Treatment of School Children in Barry.

In an appendix to his second annual report to the Barry education committee Mr. W. Lloyd Edwards, the school medical officer, places before that authority a scheme for the treatment of those children found on medical examination to be defective. He points out that this examination reveals two types of ailments which require treatment. The first includes errors of refraction, the presence of adenoids or enlarged tonsils, and dental defects, while the second includes ailments requiring ordinary medical treatment. He suggests that for the first class of cases special medical men should be appointed who would be paid at the rate of £50 per annum for an attendance of one afternoon weekly, and that the total sum necessary, which he estimates at from £350 to £400 per annum, should be raised by contributions of 1*d.* a month from the parents of the 7000 or 8000 children in attendance at the schools. Where the parents could not afford to pay he proposes that the amount should be paid by the education authority, and that the board of guardians should pay for the 350 children under its care. To deal with the second class of cases he suggests the formation of a school medical service, on the staff of which all the medical practitioners in the town should be invited to serve. They would receive in payment for their services the sum of 3*s.* per annum for each child, contributed by the parents of those children who were included in the scheme. At the beginning of each year the parents would have the choice of the medical man to attend upon their children. The expenses of administration both of the clinic and of the school medical service it is proposed should be defrayed by the education authority.

Newport School for Mothers.

For several years past the medical officer of health of the county borough of Newport, Dr. J. Howard-Jones, has drawn attention in his annual reports to the waste of infant life in the borough, which he considered was largely due to the ignorance and want of appreciation of the importance of domestic hygiene on the part of mothers. In 1908 the infantile mortality-rate in the whole town was 135 per 1000 births, a considerable decrease on the rate recorded in some previous years, for in 1899 it was as high as 188 per 1000. In 1908 the rate varied very considerably in different parts of the borough, in one portion being as low as 95 per 1000 and in another as high as 200 per 1000. These figures all point to the need for some systematised instruction of mothers on the lines indicated by Dr. Howard-Jones. Such instruction and other suitable assistance have been made possible through the establishment of an Infantile Health Central Committee which has recently issued its first annual report. The work of the committee is being carried out very much on the lines of the St. Pancras School for mothers. Milk is supplied to necessitous mothers and expectant mothers, to the former only on the distinct understanding that she suckles her child. Twice a week mothers are invited to the centre where the health visitor talks to them on matters of hygiene, feeding, clothing, and the general care of babies. At other times a class is held for instruction in the cutting out of clothes. Although so recently established and conducted on modest lines there is already evidence of good resulting from the efforts of the committee.

Appointment of Medical Officer of Health for Merionethshire.

Merioneth county council has decided to appoint a medical officer of health for the county, his duties to include the medical inspection of school children, at a salary of £450 per annum, including travelling expenses, a knowledge of Welsh being necessary.

June 7th.

THE degree of Master of Laws in the University of Cambridge has been conferred upon Mr. D. Cotes-Preedy, M.A., L.S.A., Barrister-at-Law, honorary secretary of the Medico-Legal Society, and late house physician at St. George's Hospital, for a dissertation entitled "The Legal Relations of Hospital Authorities, their Staff and Patients."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Sir Hector Cameron's Resignation.

IT is with great regret that we learn that Sir Hector C. Cameron has presented a petition to the Court of the University of Glasgow for leave to resign from the chair of Clinical Surgery. Sir Hector Cameron, who has long been recognised as one of the leading Scottish surgeons, was educated at St. Andrews, Edinburgh, and Glasgow Universities, and received his early training under Lord Lister in the Royal Infirmary, Glasgow, where he was house surgeon, while he also assisted Lord Lister in his private work. Subsequently he became surgeon to the Royal Infirmary and was engaged in that capacity from 1874 to 1881, when he was appointed to a similar post in the Western Infirmary. It was during his presidency of that body that the Faculty of Physicians and Surgeons of Glasgow celebrated its tercentenary, and ten years ago Queen Victoria conferred upon him the honour of knighthood.

A New Medical Novelist.

A work of fiction, entitled "My Lady of Aros," has recently appeared from the pen of a writer who has assumed for literary purposes the name of John Brandam. The book will appeal to your readers when they know that the author is a medical man who practised for some years in the island of Mull—otherwise Aros—where the scene of the story is laid, and was formerly a distinguished student of St Mungo's College, Glasgow, a "John Reid" prizeman, and a resident physician and surgeon at the Royal Infirmary, Glasgow. In moments of leisure from his widely-scattered practice he has written a book, and, a Celt himself, in his professional work he has found an opportunity of dissecting and understanding the aspirations and ideals of the Celtic nature.

Transfer of Sidlaw Sanatorium.

As Monday, May 30th, was the last day upon which objections to the Bill for the transfer of the Sidlaw Sanatorium to the directors of the Dundee Royal Infirmary could be lodged, and as no objections have been lodged, the passage of the Provisional Order is secure, although it will probably be August before the Order is passed.

June 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Association.

THE annual meeting of the Irish Medical Association was held last Tuesday at the Royal College of Surgeons, Dublin, Sir Thomas Myles, the President, being in the chair. The report of the Council stated the membership as 629, being a decrease of 63 from that of the previous year. The Council notes its failure to obtain any better terms from the Treasury in payment for the weekly returns made by registrars of deaths of persons over 70 in connexion with the working of the Old Age Pensions Act. The Council failed also to secure coöperation between veterinary surgeons and medical officers of health in the carrying out of their duties under the "Dairies and Cowsheds Order" of the Local Government Board. The Council endeavoured to obtain some concession from the colleges and hospitals by way of reduction in fees for the children of medical men preparing to follow their fathers' profession. Sympathetic replies were received from the Royal College of Surgeons and Trinity College, Dublin, and the Council is hopeful of being ultimately successful. The Council endeavoured to induce the Local Government Board to place Poor-law medical officers, when subpœnaed to attend a court of law in private cases, in the same position as if they were Crown witnesses. While it has not been successful, at the same time it is pleased to state that in one case brought under the notice of the Local Government Board by the Association the Board recommended the board of guardians to pay the substitute. The income received, with the balance in hand at the close of last account, amounted to £967 0*s.* 4*d.* and the payments to £542 16*s.* 9*d.*, leaving a balance of £424 3*s.* 7*d.* In the journal account receipts amounted to £30 12*s.* 3*d.* and the

expenditure to £199 0s. 3d., showing a net cost to the Association, £168 8s. 0d. The arrears account at the end of 1909 stood as follows: 69 members owed two years' subscription, 94 owed for one year, and 2 owed 10s. 6d., making a total of £244 13s. 0d. The balance-sheet showed assets £729 16s. 7d. and liabilities £7 8s. 10d., leaving a surplus of £722 7s. 9d. Mr. O'C. Delahoyde has become honorary treasurer of the Association in room of Sir William J. Thompson, who resigned upon his appointment as Registrar-General. It was announced at the meeting that a plebiscite of the members had recently been taken on the question of a national medical service. 295 expressed themselves in favour of a national service and 46 against.

The Royal College of Surgeons in Ireland: Election of Officers.

The following are the results of the annual elections which took place at the last meeting of the Royal College of Surgeons:—President: Robert H. Woods. Vice-President: Richard D. Purefoy. Honorary secretary: Sir Charles A. Cameron, C.B. Council: Sir Henry R. Swanzy, William Stoker, Sir Charles Alexander Cameron, C.B., John B. Story, Sir Charles B. Ball, Sir Thomas Myles, John Lentaigne, Sir Arthur Chance, Sir Lambert H. Ormsby, Henry G. Sherlock, R. Bolton M'Causland, F. Conway Dwyer, R. Lane Joynt, William Taylor, Edward H. Taylor, R. Charles B. Maunsell, William Ireland Wheeler, D. Edgar Flinn, and Thomas E. Gordon. There was no contest for any of the offices, as the other gentlemen who had intended to stand for the vice-presidency withdrew their candidature. There is no change on the Council except that Mr. Conway Dwyer succeeds to the place from which Mr. G. Jameson Johnston retired on his election as an examiner. Mr. Dwyer is surgeon to the Meath Hospital and professer of surgery in the College school. Previous to the election there were many rumours of probable changes, as the "progressive" policy of part of the Council in relation to the school had roused some opposition. As will be seen, this opposition was not strong enough to dislodge any members of Council. Whether this is due to approval of their policy by the Fellows in general or to mere inertia cannot be stated.

The Royal College of Surgeons in Ireland: Report of the Council.

The annual report of the Council of the Royal College of Surgeons in Ireland, which has just been presented, states that during the year 27 candidates were admitted to the Fellowship; 73 candidates received the Conjoint Diplomas in Medicine, Surgery, and Midwifery, of the Royal Colleges of Physicians and Surgeons; 37 candidates received the Conjoint Diploma in Public Health of the Royal Colleges of Physicians and Surgeons; 10 candidates received the Licence in Dental Surgery. 81 candidates passed the Conjoint Preliminary Entrance Examination with the Royal College of Physicians. The obituary list shows that 12 Fellows and 51 Licentiates died during the year. There are at present living 12 Honorary Fellows, 486 Fellows, 2919 Licentiates, 6 Honorary Diplomates in Public Health, 334 Diplomates in Public Health, and 548 Licentiates in Dental Surgery. "During the past year," the report runs, "a large sum of money, amounting to nearly £1400, has been expended on the Anatomical Department, the most important department in every medical school. The old floor, saturated with disease germs, has been replaced by one more in accordance with modern ideas. A new system of ventilation has been installed, new tables of modern type have been supplied, the walls have been thoroughly cleansed and re-painted, the preparation room completely renovated, and large preserving tanks have been provided for the convenience of the anatomical class." Regret is expressed regarding the death of Professor A. Fraser, and it is announced that a Civil List pension of £70 a year has been granted to Mrs. Fraser. A branch of the Officers' Training Corps has been established in the College and the Council aided the students in the formation of a students' branch.

The Royal Medical Benevolent Fund Society of Ireland.

The annual meeting of this society has just been held. The report states that, including a balance of £758 16s. 2d. from the preceding year, the income of the society in the financial year ended on April 30th amounted to £2408 1s. 4d., which was less than that of the preceding year by £206 10s. The difference is very nearly accounted for by the receipt last year from the Royal College of Surgeons of £202 18s. 7d., accumulated interest of the Carmichael Prize Essay Fund. On the credit side of the account the disbursements amount to £1610 7s. 1d. Grants awarded to 86 applicants amounted to £1438 2s. 6d., as compared with £1166 awarded to 83 applicants the preceding year. The average amount awarded for the last eight years was £1184. In only one year since the society was instituted did the grants awarded exceed those of the year now ended. In 1879–80 they amounted to £1445 7s. 6d. In that year £400 were granted to 12 medical men, as compared with £155 awarded to four medical men in the year now ended. The society is doing excellent work and deserves more hearty support.

The Antituberculosis Campaign in Ireland.

The Countess of Aberdeen, as the President of the Women's National Health Association of Ireland, has been able to make the announcement that there is a distinct reduction in the annual death-rate from Ireland's fell scourge, tuberculosis. The Registrar-General, Sir William J. Thompson, has placed in her Excellency's hands an advance copy of the statistics for 1909. According to these, the deaths from all forms of tubercular disease were 11,679 in 1907, 11,293 in 1908, and 10,594 in 1909—last year—thus showing a decrease of 699. That was a total decrease of over 1000 in two years. The death-rate per 1000 was 2·7 in 1907, 2·6 in 1908, and 2·4 in 1909. To put it in another form: in 1907 there were on the average 32 deaths in Ireland every day from tuberculosis, while in 1909 the daily average was 29 deaths, which meant that at present there were about three deaths a day less in Ireland than two years ago. Again, the death-rate, 2·4, was the lowest that had been reported for 35 years. In announcing these most gratifying results at a meeting of the Women's National Health Association held in Dublin on June 6th, Lady Aberdeen explained that the association did not mean to claim all the credit for the reduction in the death-rate, but they thought that they had something to do with it. They wanted, she said, to make this the occasion of an appeal to all such associations, and especially to the members of their own association, who should be encouraged to press forward to even greater efforts. She also announced that a French medical society had awarded a medal to the Women's National Health Association.

Extension of the Midwives Act to Ireland.

At the annual meeting of the Ulster branch of the British Medical Association, held in the Medical Institute, Belfast, on June 2nd, the President, Dr. T. H. Moorhead, being in the chair, on the motion of Sir John Byers, seconded by Mr. R. J. Johnstone, a resolution was passed unanimously approving of the extension of the Midwives Act of 1902, as amended, to Ireland.

Proposed Increased Hospital Accommodation in Belfast.

Under the auspices of the Lord Mayor and Lady Mayoress of Belfast, the former of whom presided, a meeting was held in the City Hall, Belfast, on June 6th to initiate a movement to complete the fund for the rebuilding the Ulster Hospital for Children and Women. From £10,000 to £12,000 will be required to erect and equip the new building, and the board of management has decided not to lay a single brick before the whole of that amount has been secured. Already considerably over £7000 have been paid or promised, and it is in order to raise the remainder that this meeting was held. Admirable speeches were delivered, especially on the medical side by Dr. A. B. Mitchell, who is surgeon to the institution, and a strong committee of ladies was appointed to collect the necessary money required.—It has been suggested that as a memorial to King Edward VII. a sum of money should be raised sufficient to open the two wards in the Royal Victoria Hospital, which owing to want of funds are still closed.

Bangor (County Down) Cottage Hospital.

At the annual general meeting of the supporters of this hospital held recently, it was reported that the new hospital would cost about £3400, without providing for laying out of the grounds. It will be finished in about three months time. A sum of £2379 has been paid in aid of the building, while £300 were promised, leaving a balance of £700 needed, for which the committee makes an urgent appeal.

June 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disorderly Scenes at the "Concours pour l'Agrégation."

THE examination known as the *Concours pour l'Agrégation*, which was held recently at the Paris Faculty of Medicine, has been the occasion of a remarkable series of disturbances. Previous letters in this column have shown that in medical circles there is much hostility to this examination. In particular the Congress of Practitioners has several times voted in favour of suppressing it, and at the last meeting of this congress two months ago the members resolved to use every endeavour to prevent the holding of the present examination. The results of these competitions are said to depend entirely on personal interest, the examiners giving preference to their favourite pupils. The system of *professeurs agrégés* selected by competitions of this kind has also been energetically attacked on the ground that the successful candidates are young men owing their positions to favouritism, that the instruction which they give is entirely theoretical and useless, and that it would be preferable to have the requisite instruction given at hospitals by all medical men who might consider themselves capable of acting as teachers. The competition which ought to have taken place two years ago gave rise to such disturbances that the Minister had to close the proceedings, and as a measure of pacification promised that an inquiry should be held by a commission consisting of one half professors and one half practitioners. This commission has never been appointed and the malcontents now avail themselves of this breach of faith as a reason for attacking the present *concours* more violently than ever. A meeting has been held to draw up a list of candidates, and the law requires this, like all the other work of the *concours*, to be done in public. One of the first manœuvres of the hostile faction consisted in an unheard-of number of candidates giving in their names, for all doctors of medicine are legally eligible. Crowded together in the ampitheatre where the list was being drawn up in presence of the jury, they set up such a noise that the dean, who was president of the jury, could not make himself heard, and in order to communicate with the meeting had to write on the blackboard what he intended to say. At the same time fruit and eggs were thrown by the audience at the jury, who endured this onslaught with stoic fortitude, disregarding the yellow splashes which the eggs had made on their handsome robes of cerise silk. After two hours of uproar the list of candidates was completed and the proceedings terminated. The meeting on the following day was particularly stormy. Numerous police officers were in attendance and the process of drawing lots went on for two hours amid shouting. An egg being now thrown the officers rushed into the part of the amphitheatre from which it had come and without discrimination arrested six persons, almost all of whom were manifestly innocent. The president then had to declare the proceedings closed on account of the commotion. The Association of Medical Students, which up to the present time has remained neutral, has now resolved to take action for the purpose of entering a protest against the conduct of the police.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

King Victor Emanuel at Messina.

"SURPRISE visits" have enabled the King of Italy to detect the culpable supineness (or worse) of the local authorities in the earthquake-damaged districts of Calabria. But official visits like that just paid by His Majesty and Queen Elena to Messina seem not less fruitful in disclosing the negligence of those charged with the rehabilitation of the town. Not only were the Royal pair disappointed with the reconstructive operations, still lagging wofully behind, but they were simply shocked at the insanitary conditions prevailing—prevailing, moreover, of all places in the world, in the hospital itself! The Senator Signor Todaro, for many years the able professor of anatomy in the Roman school, had the unpleasant duty of conducting the King over the Ospedale Civile, while sharing His Majesty's dismay at the filth and general slovenliness into which the wards and the operating theatre had been allowed to lapse. "Tell me," said the King to the Senator, "hygienist as you are, if it is possible to perform a surgical operation in this *luridume* (revolting dirt)." "I have just been drawing the Queen's attention to it," replied the Senator, ruefully; whereupon His Majesty, turning to the heads of the hospital administration, asked indignantly: "Are there no longer soap and water in the world? Excuse my frankness, but these poor patients, it would seem, have only Providence to rely upon!" Such is the return vouchsafed by officialdom in Messina to the generous largess of a sympathising world!

The "Bitter Cry" of the Communal Practitioner.

The debate still in progress on the "Bilancia dell Interno" (Budget of the Home Office) elicited some facts that were encouraging, but many more that were disquieting in the conditions under which the "medico condotto" lives and labours. Working in terms of the "Codice Sanitario" prepared by Bertani, the able Garibaldian surgeon, and reduced to practice by Crispi in 1882, the communal practitioner has succeeded in lowering the death-rate in the rural districts considerably, but with the increasing complexity of his task and the multiplying causes of friction between him and the "authorities," his lot, becoming daily harder, is now well-nigh intolerable. His spokesman in the Chamber of Deputies was Professor Angelo Celli, who described in trenchant language the difficulties and impediments the "medico condotto" has to struggle with, thanks to a bureaucratic system which seems expressly contrived to thwart individual effort. Under that system there is a fatal want of laboratories organised for sanitary surveillance, of isolation huts or houses, of the means of disinfection on up-to-date lines; while alcoholism, continued the orator, with its disastrous sequelæ, is actually promoted by the new law of "Sunday repose" and the opening of the public-houses. Nothing, moreover, is being done against tuberculosis; while as to pellagra, the means of combating it are vitiated by adherence to a theory of its cause which has collapsed before twentieth century research. The conditions under which the "medico condotto" has hitherto served are now impossible, contended Professor Celli, and what is the result? "The profession is ceasing to be attractive; the number of medical students in the universities is declining; the schools of pharmacy and veterinary surgery are deserted; and all this (and more) because nothing is being done for the 'classe sanitaria' (the practitioner class)." Professor Celli may have erred on the side of "special pleading," but his speech has made a profound impression not on the Chamber only. As reported in the press, it will have an effect on the constituencies which must make the rehabilitation of the "servizio sanitario" and of the "classe sanitaria" a *conditio sine quâ non* of any candidate's winning a seat in Parliament.

Italy's Tribute to Robert Koch.

Not only in the Chamber of Deputies has honourable reference been made to the career, as universally beneficial as it was academically and clinically brilliant, of the great German bacteriologist, but all through Italy, particularly in the centres of nature study and medical training, has that reference found a sympathetic echo. Italians, in truth, are deeply sensible of what the exact sciences, and, above all, those on which the practice of medicine is based, owe to the foreigners—German, Dutch, French, and British. Moleschott, migrating from his native Holland to Zürich, and thence brought by the great Cavour to Turin, initiated a salutary revolution in the teaching and the study of physiology through Italy, many of her most accomplished and effective occupants of physiological chairs having been his pupils. Dr. Boll, who died all too young, was another life-giving importation into Rome from beyond the Alps; while the sculptured presence of Lister on the façade of the surgical pavilion of the polyclinic attests the national homage to the English pioneer. And now Robert Koch is the theme of the most ardent eulogy—pupil after pupil at present employed in Italian laboratories coming forward to declare the debt they owe to him. This "fraternising" spirit is of happy augury,

not only in science, but (let us hope) in other international relations—even that of gradual disarmament and eventual peace!

June 2nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Unique Obstetrical Event.

FOR some time past considerable interest has been felt in medical and other circles on account of the news that one of the well-known "Siamese" twin sisters had given birth to a child. The twins were born in Prague and are now 36 years old. They have been exhibited all over the world, and it seems that during these travelling tours one of them fell in love with their manager; her twin sister, however, pretends that she knows nothing at all of the circumstances. A few weeks ago they had to see a surgeon in Prague on account of supposed colicky pains in the abdomen of one of them, who had been operated upon several years ago for cholelithiasis. The sisters and their father thought that a recurrence had taken place, but the surgeon diagnosed advanced pregnancy, or rather an incipient labour. The possibility of such an event being flatly denied by the sisters, a consultation with a leading obstetrician was arranged, but before his arrival the matter was cleared up by the woman being delivered of a healthy male infant. A few days ago the twins were examined and shown by Professor Schauta before the students at his clinic in Vienna. They are healthy looking, normally developed individuals, but are united to each other in such a way that their os sacrum is common to both. Each vertebral column of the twins is twisted through an angle of about 45° along a vertical axis when they are standing upright. They have only one anus, one clitoris, and one vagina, into which two uterine canals open. It is not possible to determine exactly the condition of the internal organs. The metabolism of each woman is completely independent of that in the other. Thus, for instance, whilst the mother and her twin sister felt the pain of labour alike, the mother showed a temperature of 38° C. on the second day, whilst her companion had a normal temperature. On the other hand, both women have milk in their breasts. Hunger and thirst are independent in the two; sexual impulse and the desire for micturition are always much stronger in the one who has become a mother than in her sister. Professor Schauta said that this was the first instance of one of a pair of conjoined twins having given birth to a healthy infant. As regards the anatomical location of the organs common to both sisters, there are no openings between the thighs of each individual of the pair, but the anus, rectum, and vagina (the two latter being well separated from each other) are situated between the two women as it were. There are two orifices of the urethræ leading through separate canals into separate bladders. The labour was normal and easy, the child being small and born at full time. The examination will be continued, and also observations of metabolism and mental conditions have been arranged for, so that the scientific investigation will be complete in due time.

The Vienna General Polyclinic.

The Vienna General Polyclinic has just issued its report for the year 1909, and some of the particulars are worth mentioning. The institution is one of the few of its kind in Austria which are supported by voluntary contributions and has been in existence for 30 years. The medical staff consists of 14 professors, with 4 house physicians and 60 other medical men in the various out-patient departments. The number of beds is 150, including 30 cots for children. The hospital possesses all arrangements for treating all diseases; a well-equipped electrical department with an X ray outfit and a stock of radium has been added recently. In connexion with the surgical department there is a gymnastic hall for children. The number of out-patients during 1909 was 77,000, being 5000 more than during the previous year, whilst 3011 in-patients were received in the wards; 834 children of various ages up to 14 years were admitted into the children's department. The mortality was 10 per cent. Over 17,000 minor operations were performed in the in-patient and out-patient wards, and over 1500 major operations, with a mortality of 6 per cent., were reported. In spite of the most careful economy there was a financial deficit of over £2000, a result which is made more remarkable by the fact that all the appointments, except those of the two resident assistants, are purely honorary. The hours of attendance in the out-patient department are from 8 A.M. till 8 P.M., and numerous classes are held in which both German and English are spoken, so that the clinical material is sufficiently utilised. Some of the staff are celebrities in their respective branches, such as Dr. von Frisch in urology, and Dr. Alexander in otology. Other well-known members of the staff were Professor Spiegler and Professor Monti, both of whom are now deceased, and formerly also Dr. Hochenegg and Dr. Basch.

Surgical Treatment of "Crises Gastriques."

At a recent meeting of the Medical Society of Vienna Dr. Moszkowitz and Dr. Gözl showed a man who had been suffering from frequent attacks of *crises gastriques* and had been brought to such a degree of despair that he was prepared to undergo any form of treatment which gave promise of relief. The two surgeons resolved to divide the posterior roots of certain spinal nerves. They selected the seventh, eighth, and ninth roots and divided the dorsal portions which contain the sympathetic fibres leading to the stomach. Since the operation the patient has lost his former distressing symptoms of incessant pain, vomiting, and mental depression. He has also gained weight, and the only outward symptom due to the operation is an anæsthetic zone around the abdomen. Further observations will evidently be necessary for forming a definite opinion as to the value of the operation.

June 6th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

A New Medical Centre.

THE munificence of a few St. Louis millionaires has rendered possible the accomplishment of a long-felt necessity. St. Louis is the geographical centre and natural metropolis of the middle west and south-west of the United States, and the recent gift of several millions of dollars to the medical department of Washington University in St. Louis will enable it to become a serious rival to Johns Hopkins. New buildings, to include a general hospital, an obstetric hospital, a children's hospital, with all the necessary laboratories and dispensaries, &c., are to be erected on an ideal site overlooking the beautiful Forest Park, on which the World's Fair of 1904 was held. First-class teachers are to be brought from wherever they can be obtained, and their time is to be wholly devoted to teaching and research. The appointments already made are those of Dr. George Dock, formerly of the University of Michigan, but at present of the Tulane University, New Orleans, to the chair of medicine; of Dr. John Howland, of University and Bellevue Hospital Medical College, New York, to that of pædiatrics; of Dr. Eugene L. Opie, from the Rockefeller Institute, to that of pathology; and of Dr. Joseph Erlanger, of the University of Wisconsin, to that of physiology. The new chairs of medical chemistry and preventive medicine, as well as the chairs of surgery and pharmacology, are awaiting appointments. There is to be an adequate corps of teaching assistants to these chairs. This development of Washington University Medical Department, added to the vastly increased facilities for clinical teaching in St. Louis, effected by the utilisation for clinical instruction of the vast material of the various municipal hospitals by a visiting staff to be created by the new Hospital Commission, will surely go far towards putting St. Louis in the foremost rank in the United States as a centre of medical instruction, both pre-graduate and post-graduate.

The National Conference of Charities and Correction.

At the present time St. Louis is the centre of observation in view of the great number of conventions that are meeting here in rapid succession. On June 6th the American Medical Association, with its subsidiary societies, holds its annual session here. This week is taken up with the Thirty-seventh National Conference of Charities and Correction, under the presidency of that remarkable woman, Miss Jane Addams of

Chicago. At the opening session on May 19th, in the presence of upwards of 2000 people, Governor Hadley of Missouri fired a gun at the pernicious and blighting system that prevails nearly all over the United States, in respect of the municipal eleemosynary institutions and sanitary governments. He promised to lay before the next meeting of the Legislature a Bill to place all these institutions under one board of men chosen solely on their scientific qualifications, instead of, as at present, each institution having its own board appointed on political partisan lines. It seems utterly ridiculous that the public health officials and those of the city hospitals should owe their positions to their political affiliations; yet such is the case in most cities, not St. Louis only. In her presidential address Miss Addams gave a masterly analysis of the motive forces underlying the social work of to-day. She divided the great body of social workers into those who work "for the love of the poor" and those who labour out of "hatred for injustice." "The negative policy," she said, "of relieving destitution, or even the more generous one of preventing it, is giving way to the positive idea of raising life to its highest value." She instanced the changes arising from the movement to control and eradicate tuberculosis as illustrating rapidly and graphically the social advance due to sanitary science, and cited the instance of a recent exhibition in Boston at which was shown an incandescent lamp that flickered into darkness twice a minute to indicate the rate of deaths from tuberculosis in the world, while, near by, the knife of a miniature guillotine fell every ten seconds to show the rate of industrial accidents in the United States. This, she said, illustrates "the wonderful methods of popular instruction which the destroyers of the white plague have evolved." Among the subjects receiving prominent attention at the conference are the present harmful system of treating insane wrong-doers as law-breakers and confining them in jails as prisoners when they should be in hospitals or asylums as patients; the bringing up of homeless children in institutions when they ought rather to be boarded out in homes; the crusade against tuberculosis; the development of the ideal city; the caisson worker and his diseases; rescue work among women; the payment of living salaries to widows to enable them to stay at home and bring up their children, a plan in actual operation by the Jewish charities; the sanitary condition of the "slums," of which the "Ghetto" in St. Louis is an awful example; and the "murder account" of factory work among women and children. The conference was preceded by one on backward and delinquent children.

May 25th.

THE Asylums Committee of the London County Council have received with much regret the resignation of Dr. David Johnston Jones, the medical superintendent of Banstead Asylum, after 30 years' service, 20 of which have been rendered at that asylum. Dr. Jones has been medical superintendent since Oct. 1st, 1901. The committee, in accepting Dr. Jones's resignation, say: "We gladly avail ourselves of this opportunity of recording our appreciation of Dr. Jones's faithful service and his sympathetic care of the patients."

DONATIONS AND BEQUESTS.—The late Mr. Alfred Shipley of Bristol has left by will £1500 to the Bristol General Hospital, £1000 to the Bristol University, £500 each to the Bristol Royal Infirmary, the Bristol Children's Hospital, and the Winsley Sanatorium, £200 to the Bristol Eye Hospital, and smaller sums to other charities. —By the will of Miss Harriet Sydney Hughes the testatrix left her residence, Bryn Menai, Bangor, to the Queen Victoria Jubilee Institute for Nurses as a house of rest or convalescent home for nurses, and a sum not exceeding £6000 for its upkeep; £500 to the Carnarvonshire and Anglesey Infirmary; and £300 to the Bangor District Nursing Association.—The Bristol General Hospital has benefited to the extent of £1000 under the will of the late Mrs. Markham Skerritt.—Among other charitable bequests, the late Mrs. Helen Crowther, of Rochdale, has left £4000 to the Rochdale District Nursing Association, £3000 to the Rochdale Infirmary, £1000 to the Pendlebury General Hospital, a similar amount to the Dispensary for Sick Children, and £500 to the Rochdale District Blind Society.

Obituary.

SIR FRANCIS SEYMOUR HADEN, F.R.C.S.

THE medical profession and the artistic world alike have lost a well-known figure by the death of Sir Francis Seymour Haden, which occurred on June 1st at Woodcote Park, Bramdean, Hampshire, his country seat. Widely famed as an artist, his medical career was distinguished, while his work as a sanitarian was also vigorous and valuable. Francis Seymour Haden was born on Sept. 16th, 1818, being the son of Dr. Thomas Haden, a graduate of the University of Edinburgh, who practised in Chelsea. He was educated at University College School and studied medicine first at University College, London, whence he went, as was at the period the recognised thing for the more ambitious young men to do, to the medical school of Grenoble and to the Sorbonne in Paris. He graduated in 1839 as M.D., while in France, and became a Member of the Royal College of Surgeons in 1842, 15 years later proceeding to the Fellowship. In Paris a hereditary taste for art—his grandfather was a painter—coupled with the fact that the value of drawing had been insisted upon in his educational courses, made him resolve to perfect himself as a draughtsman. He took lessons regularly at an art school while he was studying in Paris, and his appointment at the early age of 33 years to be honorary surgeon to the then Government Department of Science and Art still further confirmed his bias.

The first purely professional work which brought him into prominence was his report in connexion with that department upon the progress of modern surgery. This report was issued for the International Exhibition of 1862, at which exhibition a very remarkable display of surgical instruments of all sorts was given. A long and detailed account of the instruments at this exhibition was published in THE LANCET as a series of articles, and the descriptions supplied of the uses of the armamentarium of the day form an interesting and valuable commentary upon the position of surgery. Haden's official report upon the instruments, made for the international jury which had been convened to adjudicate upon the progress of surgical science during the decade 1852–62, went over the same ground in many places, but gave a really exhaustive history of operative surgery for these ten years, and was, besides other things, remarkable for its outspoken advocacy of ovariotomy. Among the most important indications of progress in surgery which he illustrated by reference to the instruments exhibited are revival of the excision of certain joints; the radical cure of reducible herniæ; new methods of external and internal urethrotomy; improved means of extracting foreign bodies from the bladder *per vias naturales;* the revival of median lithotomy by Allarton; improvements in lithotomy and ovariotomy; successful closure of recto- and vesico-vaginal fistulæ; the employment of metallic sutures; the division of vascular tissues without hæmorrhage by *écrasement linéaire;* improved methods of treating aneurysm, by compression, by flexion, and by coagulating injections; acupressure; subcutaneous injections; and the electric cautery. Thus it will be seen that he travelled over a wide field, and, being relieved from the necessity of explaining details of construction by referring to the articles in our columns, acknowledgment of which assistance is made freely, he was able to give his report a connected interest which made it both pleasant and highly instructive. "It may well be a source of pride and satisfaction to British surgeons," we said in reviewing this report, "to look through the list of improvements in surgery, to be able to reflect how large a portion of them, and especially how important a part, may be claimed as belonging to the work of the British school. The great progress in ovariotomy, lithotomy, the radical cure of rupture, and the treatment of aneurysm belongs to the British surgeons, not to speak of the multiplicity of practical improvements in each of the other departments." Haden showed his independence in dealing in an outright manner with one delicate point. He was compelled to face the question of the existing relations between surgeons and instrument makers. With honourable exceptions, it had largely been the tendency of the makers to claim for themselves the invention of instruments, of which the pregnant

idea had been suggested to them, and entrusted for elaboration to their mechanical skill; while many surgeons complained that the makers frequently suppressed, as far as possible, the names of those from whom they had derived their inspiration. It was a subject of remark, in connexion with the labours of the jury over whom Haden presided, that only rarely did the makers give to the jury any assistance or information on this head. Haden gave a list of scientific and other contributors to the exhibition who were not ostensible exhibitors, but whose inventions, exhibited by others, were alluded to in the report. Many inventors no doubt remained unnoticed, but he laboured hard to do justice to all. For this he deserved the thanks of all surgeons, his action putting a stop to an abuse that seems to us in this day of an incredible and foolish kind.

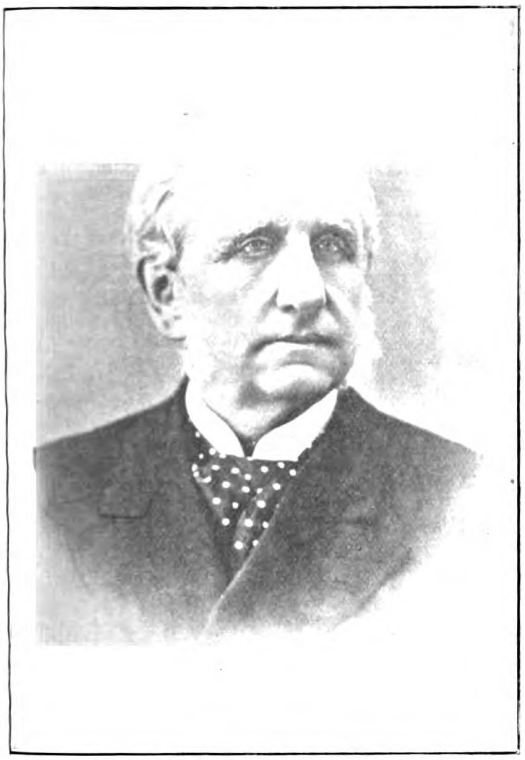
The operation of ovariotomy, as we have said, found an able supporter in Haden. Practitioners were at this time divided with respect to its value as a surgical proceeding, and Lister's discoveries had not made sufficient progress to be a commanding factor in the questions at issue. The tendency, on the one side, was to over-estimate the value of the operation, having regard to the results as yet obtained; on the other hand, it was unjustly depreciated by many leaders of medicine. What was wanted was a more clear description of those cases in which the operation could be safely practised, and not wholesale assertions as to the facility with which the proper cases for operation could be determined, nor general condemnations of the proceeding, with exaggerations of the difficulties of diagnosis, for these methods of treating the question had no other effect than to involve it in still further obscurity. It must be admitted by anyone who studies medical literature of the year 1862 that acquaintance with the nature of ovarian disease was not so complete as the advocates of ovariotomy asserted, even if no one was quite so ignorant respecting it as the opponents of that operation unhesitatingly contended at the meetings of the learned societies. The numerous discussions showed that whatever had hitherto been the success of ovariotomy in the hands of certain operators, the diagnosis of ovarian disease was by no means without its difficulties, nor the simple operation in its simplest form without its complications and dangers. The leaders of obstetric medicine, especially some of the veteran specialists, regarded the operation on the whole with a sharply critical eye, so that Haden's advocacy of the procedure was a bold line to take, and he took it with a spirit which proved him to be sincere to his convictions.

In 1867 Haden resigned his post under Government and devoted himself mainly to etching, though he had a good private practice; he also made frequent pronouncements upon one subject very dear to his heart as a sanitarian—viz., the reform of our methods of burial. He carried out an investigation into the conditions of many London graveyards, and came to the conclusion as a result that earth-to-earth burial was the only safe and decent mode of sepulture. Of cremation, which he considered wanton waste of material required by the soil, he was as declared an enemy as he was of the usual methods of earth burial. Thus he denounced brick vaults, lead shrouds, and even oak coffins as strongly as he denounced the funeral pyre; while he invented a perishable coffin composed of papier-mâché, designed to allow the corpse as quickly as possible to come into contact with the soil, his contention being that it was absurd to enclose bodies in hermetical coffins, so that neither the air nor the earth could gain access to them. Haden's assertion, made often and fiercely, was that the natural destination of all organised bodies is the earth—"Everything that has lived dies and everything that dies falls to the earth." The view has a good deal of force, although the evils which he described in his diatribes against burial usage were not always dependent on the methods of interment adopted. He was obviously without fear of premature burial as a danger that was even worth considering, for in addition to condemning the practice of using strong coffins and brick vaults for the reception of corpses, he condemned the lengthy period often permitted between a death and the succeeding burial. "Retention in dwelling houses after putrefaction has set in," he wrote in our columns, "necessitates the use of a strong coffin, which is the cause of all the evils." His views on the subject have on numerous occasions received notice in the columns of THE LANCET. The chief amongst the articles which he has contributed on the subject are: "Note on the Disposal of Dead Bodies,"[1] and "Remarks on Proper and Improper Burial, with an Examination of the Claims Made for Cremation."[2] He was also much interested in the foundation of the Hospital for Incurables. He advocated the movement vigorously and was a liberal donor to the funds in the early days of the movement, while he also signed a medical testimonial to the value of the institution for circulation to the public, among his co-signatories being Professor Sharpey, Sir William Fergusson, Sir Prescott Hewitt, and Sir Richard Quain. His name appears in the list with the quaint qualification of consulting surgeon to the Chapel Royal Fund.

As a medical man, Haden, able and very well informed as he was, took no high official or scientific place, but he made his mark. As a sanitarian he confined his researches and writings mainly to an advocacy of the reform of burial and a criticism of cremation, so that here again his scope was too limited to gain for him any lofty position despite his shrewd and vigorous powers of argument. But in the art world he was a commanding figure. He was a reformer and an organiser as well as a finished artist, and he has left his imprint for ever by his services to his own department of art—etching. It is not our business to attempt to place Sir Francis Seymour Haden in any category of etchers according to his merits, but he was recognised by connoisseurs and artists alike to be a remarkable executant, and many of his compositions have a beauty which demands for its appreciation neither technical knowledge nor critical faculty. Ability both to obtain the admiration of his craft and to win the appreciation of outsiders marks him as a leader. If he fell short in achievement of the excellence of his brother-in-law Whistler, he immeasurably surpassed the elaborate but mechanical performances of those who held the field before he appeared upon it. By founding the Painter-Etchers' Society he raised his art enormously in public esteem. Complete descriptive catalogues of his work have been published, and many of his plates have obtained high prices at sales.

It will be seen that Sir Francis Seymour Haden was a many-sided and distinguished man. He was not a prolific writer on professional subjects, although he dealt with widely diverse subjects. Amongst his writings in our columns may be mentioned, in addition to the others referred to, the following papers: "The Suppression of the Menses Treated by Leeches to the Os Uteri," "A Table to Promote Uniformity in the Registration of Cholera Cases," "Some Surgical Proceedings in the French Hospitals," and "Notes of the First Case of Algide Cholera Recorded in London in the Epidemic of 1848."

In the year 1847 Sir Francis Seymour Haden married Dasha Delano, daughter of Major Whistler, and half-sister to James McNeill Whistler. She predeceased him. He had one daughter and two sons, one of whom, Francis Seymour Haden, C.M.G., has held many high colonial appointments.



WILLIAM ROSE, M.B., B.S. LOND., F.R.C.S. ENG.,

EMERITUS PROFESSOR OF SURGERY IN KING'S COLLEGE AND CONSULTING SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

William Rose, whose death occurred last week in the sixty-third year of his age, was born on July 18th, 1847, at High Wycombe and educated at King's College, London, entering the medical school attached to King's College Hospital in his twentieth year. He was a highly successful student, and after qualifying as M.R.C.S. Eng. and L.S.A. in 1871, he held the usual junior appointments at the hospital. He proceeded to the Fellowship of the College in 1874, and after acting as house physician at the Brompton Hospital graduated in medicine at the University of London in 1875, taking first-class honours in surgery. He then became surgical registrar to the hospital and also assisted Sir William Fergusson in his private practice. In 1876 he was appointed assistant surgeon to King's College Hospital, becoming full surgeon in 1885.

During the five-and-twenty years that William Rose served on the staff of King's College Hospital he built up for himself a great reputation as a practical surgeon, while his name became a familiar one to many generations of students because of his participation in the

authorship of the most popular text-book on surgery. The following notes upon Rose as a hospital surgeon have been sent to us by one who, having been his house surgeon, later became one of his colleagues upon the staff of the hospital :—"William Rose was essentially a practical surgeon and a teacher of practical surgery—full of experience gained by the use of his hands and abounding in common-sense. He looked upon surgical instruments and appliances as a skilled mechanic would look upon the tools he used in his trade. In his hands every instrument did its work with precision; and it was an evil day for those whose duty it was to look after them and keep them in order if, upon his operating day, he found one which was not up to the mark. To an onlooker who knew how instruments should be used it was a great pleasure to watch Rose operating. Though he had large and apparently clumsy fingers, they were in reality extraordinarily dexterous. To see his fingers working inside a small mouth when operating upon a cleft palate, or to watch him using the finest catgut in the finest curved needle in a hare-lip operation was to feel that one had met a master surgeon—one in whom coördination between brain and finger-tips was absolutely perfect. His kindness to patients under his care was a side of his character seen best by his house surgeons in charge of his beds or by the ward sisters; he was not a man to make any display of this side of his character. He would often come to the hospital at the dinner hour or at tea time in order to see for himself how the patients fared. It was no good telling Rose that such and such a patient took his food well, for, curiously enough, to say this was to create a suspicion in his mind that there was something wrong, and nothing would satisfy him but to see for himself. This was a little point upon which he was often misunderstood. He would seem to disbelieve what was told him by house surgeons and dressers, sisters and nurses. In reality, he was not so much testing their accuracy as their judgment: he was training them to be sound in making reports, and in the value of evidence which lay before their eyes. One characteristic I might well lay stress upon at a time when to some muddled minds the work of the scientific surgeon appears to be an inhumane work. Rose was devoted to animals. I well remember how the death by poison of a favourite Irish terrier upset him. The dog's body was given to me, as his house surgeon, with a request to find out the poison which had been taken. Its detection was a lengthy process, for the poison turned out to be phosphorus, but Rose's delight when it was discovered and when he knew where his reprisals should be directed was very keen. His revenge was speedy and drastic. Also he excelled as a host. The dinners which he gave to his house surgeons and dressers were functions never to be forgotten by those who participated. He was an admirable dinner-giver, and in these circumstances knew exactly how to make young men feel at their ease and how to get the most merriment out of the occasion. His joviality upon such occasions was infectious, and his downright good nature will linger in the minds of all those fortunate enough ever to have been present at one of these dinner parties. I venture to believe that there is not a man who 'dressed' for Rose who has not good reason to look back upon his six months' period of office with the greatest pleasure. All he learned in that time was thoroughly practical and of the greatest value to him in after life, and the facts were prepared for his absorption so pleasantly and with so little labour that the process was a pleasure. Everybody who worked under him, from his house surgeons down to the hospital porter, mourn his loss, and the more so knowing that his later years were full of sorrow and of suffering."

Rose's literary reputation rests chiefly on the "Manual of Surgery," which he published in conjunction with Mr. Albert Carless. This book was published in 1898, at a time when there was an urgent need for a good text-book on surgery for the use of the average student. The majority of the text-books in use at that date were either too bulky for the practical and examination purposes of the student or were of such a compact nature as to resemble surgical catalogues rather than efficient guides for students. The "Manual of Surgery" exactly filled the want of a large class of readers and a critical one—for the candidate for an examination is quick to find out what really helps him—and its persistent success proves that its favourable reception on its first appearance was fully justified. We said at the time that the book first appeared that it was no easy matter to include all that such a text-book should contain and yet not to introduce details which would serve only to overburden the memory of the student; and we found that the "Manual of Surgery" in very great part met the case. Since then we have had to review several editions of the work, and our verdict has been that it is the best text-book of surgery in English for all students who do not aim at the highest examinations, though it may, and frequently does, require supplementing in certain directions, which the teachers can indicate to different classes of learners. Amongst Rose's other contributions to surgical literature are papers on the treatment of Hare Lip and Cleft Palate, on Recurrent Aneurysm of the Superficial Femoral Artery after Ligature of the External Iliac, treated by Excision of the Sac,[1] on Removal of the Gasserian Ganglion for Severe Neuralgia,[2] on the Surgical Treatment of Trigeminal Neuralgia,[3] and also notes on a case of Double Hare-lip, on Primary Nerve Suture, and Gunshot Wound of the Knee-joint. All these contributions display him as the careful, skilful, practical surgeon that he is portrayed by his colleague in the preceding paragraphs.

In 1902 he was elected consulting surgeon to the hospital at King's College, and on his retirement from the post of professor of surgery he was made a member of the Council of the College, an Honorary Fellow, and was also appointed emeritus professor of surgery. In addition to these appointments he was consulting surgeon to the Royal Free Hospital, the High Wycombe Cottage Hospital, the Stanhope-street Dispensary, the St. John's Hospital, Twickenham, the Eagle Insurance Company, and the London and Brighton and Great Eastern Railway Companies. He continued to lead a full and busy professional life until some four years ago, and enjoyed among his colleagues as well as in his profession a well-deserved reputation for operative skill of the highest sort. At this time it may be remembered that under the severe nervous strain of a law-suit, in which he was involved as an expert witness, he absolutely broke down, and was for a short time placed in a home. From this shock he never recovered, although malignant disease did not close the sad story until last week.

ELIZABETH BLACKWELL, M.D. GENEVA, N.Y.

Dr. Elizabeth Blackwell, who died at Hastings on May 31st, in her ninetieth year, was the first woman to obtain a place upon the English Medical Register. She was born at the Counterslip, Bristol, on Feb. 3rd, 1821, the third daughter of Mr. Samuel Blackwell, a sugar refiner in that city. In the year 1832 her father, as a result of commercial losses, emigrated to the United States, where he died six years later, leaving a family of nine children. The task of supporting the family fell to the three elder sisters, who opened a school, Elizabeth Blackwell being only 17 years of age at the time, and in this manner they supported and educated their younger brothers and sisters. In 1842 the eldest son of the family obtained an opening in business and there was no longer the same necessity for the sisters to earn a livelihood by teaching, but Elizabeth Blackwell continued working, as a teacher of music more especially, with the definite intention to earn sufficient money to enable her to commence a course of medical studies. The idea of entering the medical profession is reported to have had its origin in the statement of a sick female friend that the sufferings of many women were increased by the necessity of receiving medical attention at the hands of a male adviser, a point of view taken by many of the first women who entered the ranks of medicine, but one upon which nowadays little stress is laid, far stronger arguments for equal treatment of the sexes in all walks of professional life being employed. Having determined to open the medical career to her sex, she went about the task in a business-like and brave manner.

Assured on all hands that she would get acceptance at no university, none the less, during three years which she spent in teaching music at Charleston, she studied medicine in her spare time under the private tuition of a Dr. Dickson, so that in 1847, when applying for admission to various medical schools, she could claim to

---

[1] THE LANCET, Dec. 22nd, 1883.
[2] THE LANCET, Nov. 1st, 1890.
[3] THE LANCET, 1892, Abstracts from the Lettsomian Lectures.

have had some experience. In 1847 she attended private courses in anatomy and midwifery conducted for her by two medical men in Philadelphia, and at length, in the same year and after 12 American medical institutions had refused to grant her admission, she was permitted to enter the University of Geneva in New York State, whose medical college is now merged in the medical faculty of Syracuse University. The professors of the medical faculty at the University of Geneva left the responsibility of the decision as to the advisability of admitting a woman to the medical classes to the medical students themselves. It is permitted to wonder if the professors calculated on receiving from the students a unanimous resolution favourable to Miss Blackwell's request; indeed, it is probable that they fully anticipated an expression of opinion from the students that would have justified them in imitating better known seats of learning and in declining to furnish facilities for the medical education of women; the unexpected, however, happened, and she entered the medical faculty of the University of Geneva on the invitation, as it were, of the male students. After a two years' course of study at this university, Miss Blackwell received in 1849 her medical degree, being thus the first woman medical graduate in the modern meaning of the phrase. Soon after taking her degree she visited England, but not finding it easy to pursue her medical studies in the land of her birth she proceeded to Paris, where she worked at midwifery for a year and a half in the Maternité and Hôtel Dieu Hospitals, and as a result of purulent ophthalmia contracted in the wards of the former she lost the sight of an eye. In 1850 Dr. Blackwell came to England again and spent a year in study at St. Bartholomew's Hospital, the enlightened influence of the dean, Mr. Paget (afterwards Sir James Paget), securing her admission. She then returned to America and started in private practice in New York. Patients were slow to come at first, but eventually she found herself conducting a large practice amongst women and children and winning recognition among practitioners of the other sex. In 1854, at which date she was joined by her sister Emily, who had by this time also graduated in medicine, she established a dispensary, thereby enormously increasing the clinical material under her observation, and this institution three years later developed into the New York Hospital for Women and Children. Dr. Emily Blackwell had studied medicine in the hospitals of New York, Edinburgh, Paris, and London, and had found her career made easier by the adaptability and resolution which had been displayed by her senior.

On revisiting England towards the close of 1859, Dr. Elizabeth Blackwell received a cordial welcome from many members of the medical profession in this country, while she was able, as a graduate of medicine at a recognised university prior to the Medical Act of 1858, to obtain admission to the first Medical Register. On the occasion of this visit she delivered a lecture on "Medicine as a Profession for Women" in London, addressing audiences also in Leeds, Birmingham, Manchester, and Liverpool upon the same subject. Undoubtedly she became in this way the pioneer of this movement in England. Women medical practitioners were not to have an easy path before them for some time, but her proselytising zeal showed them the road to success, and those who followed in her footsteps have shown no reluctance to acknowledge their debt to her.

During the civil war in America Dr. Elizabeth Blackwell took a leading part in arranging for the nursing of the wounded, and largely owing to her enthusiasm and powers of organisation the Ladies' Sanitary Aid Association came into being. When the war was over and the remarkable development of social life in the United States began to take place a medical school for women was founded in New York, and, as was inevitable, Elizabeth Blackwell was invited to occupy a chair, and became professor of hygiene. In this capacity she did good professional and public work, but after a time she returned to England to devote her energies more particularly to assisting the movement in her native country for the education of women as practitioners in medicine. She joined the staff of the New Hospital for Women, opened as a hospital in London in 1872, and held the chair of gynæcology in the London School of Medicine for Women. From this post she retired to pass the last years of her life at Hastings, but throughout her long life she remained in intimate touch with her medical colleagues, and never lost her deep interest in their work, and in all movements having as an objective the raising of women to positions in which, as she conceived, they could play their part fully in the betterment of the race.

Elizabeth Blackwell was a really distinguished woman. She worked untiringly for the causes she had at heart. She lived to see many of her views, which had been scouted when uttered by herself and a few others half a century previously, accepted as the commonplaces of social policy. She was actuated, as it is impossible not to feel if we read any of her numerous pamphlets, by the deepest religious sense, but she belonged essentially to that school of Christian which acts on the belief that God helps those who help themselves. Her published books and pamphlets are: "The Physical Education of Girls," "The Religion of Health," "The Moral Education of the Young, "The Human Element in Sex," "Pioneer Work in Opening the Medical Profession to Women"—a book which contains an interesting account of her childhood and other biographical details—and "The Scientific Method in Biology," and many of them obtained a large circulation. When she died on the last day of May in her home at Hastings she was in the ninetieth year of her age, and although she had been ill for some time her mental faculties were unimpaired.

Medical News.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of the above society was held on May 26th, Dr. G. F. Blandford, the President, being in the chair. During the past year 19 new members were elected; 10 died, and 4 resigned. The society consists at the present time of one honorary member, 142 life, and 149 ordinary members, making a total of 291, which, considering the number of medical men who are eligible for membership, is but a very small proportion. The advantages of the society, and the great amount of good which it does, cannot be better shown than by a short study of the balance sheet for the year. The invested funds amount to £100,550, from which was derived in interest the sum of £3124 18*s.*, £350 9*s.* 6*d.* being received in subscriptions and donations. Amongst the annuitants of the charity—namely, 48 widows and 13 orphans—the sum of £3018 was distributed, each widow receiving on an average £50, besides an additional £10 as a Christmas gift, and each orphan £12 and a gift of £3 at Christmas. The Copeland fund is a special fund which enables the society to grant to any widow or orphan already in receipt of the society's ordinary relief extraordinary assistance in special circumstances of unusual distress, such as blindness, paralysis, insanity, severe disabling accident, or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of 16 or 18 years (at which, under the society's existing by-laws, the ordinary relief ceases) for such further period as the court of directors may think fit. During the year three widows in receipt of grants died. One of these whose husband had paid in subscriptions £6 6*s.* had received £2900. Two widows were elected during the year, and on Dec. 31st there were 47 widows and 14 orphans in receipt of grants. One of the widows has been on the books since 1854 and has already received over £2250. Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years or who are life members. During the year nearly 50 letters were received from widows of medical men, who in many instances had been left practically penniless, asking for relief, but this had to be refused as their husbands had not been members of the society. The directors cannot too strongly urge upon the members of the medical profession, especially the younger, the desirability of joining the society. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross. Should any member remove beyond the limits of the society, he nevertheless continues to be a member. The annual subscription is 2 guineas; every member who has paid this sum for 25 years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant. A cordial vote of thanks was passed to the editors of the various medical

journals who from time to time insert notices of the society. The meeting closed with a vote of thanks to the chairman.

THE NEWTON ABBOT HOSPITAL.—As a result of a bazaar which was recently held at Newton Abbot the sum of £131 has been raised for the local hospital.

LITERARY INTELLIGENCE.—Messrs. Harper and Brothers announce for publication during June "The Science of Happiness," by Henry S. Williams, M.D., LL.D., author of "The Story of the Nineteenth Century Science," "A History of Science," &c. It is stated to be a suggestive account of how the results of modern science may be used in promoting the "happiness" of the age.

PRESENTATION TO PROFESSOR W. ROUX.—On June 9th Geheimrat Professor W. Roux of the University of Halle, a pioneer investigator of the mechanism of animal development, celebrated the sixtieth anniversary of his birthday. Many of his pupils and followers took the opportunity of presenting him with a *Festschrift* in two volumes, a souvenir publication consisting principally of addresses.

ST. THOMAS'S HOSPITAL.—In the recently issued report of St. Thomas's Hospital the treasurer states that the total expenditure for 1909 amounted to £63,431 1*s.* 10*d.*, while the income was £62,650 1*s.* 11*d.*, thus leaving a deficit of £780 19*s.* 11*d.* The lady almoner's report, which should be read as an appendix, describes the excellent work which is being done in the attempt to check hospital abuse by inquiring into the *bona fides* of each patient. Last year 6 per cent. of the out-patients were referred to the medical staff as being able to pay, and 9½ per cent. of the casualty cases were dismissed for the same reason. The lady almoner also endeavours so to improve the social condition of the patients that they may benefit to the full from their medical treatment. Patients are encouraged to help themselves by joining friendly societies and clubs. The workers in the department visited 3055 persons last year, the parents of sick children, maternity cases, and phthisical patients being the classes who received most attention.

KING EDWARD VII. SANATORIUM, MIDHURST.—We have received a copy of the third annual report of the King Edward VII. Sanatorium, which covers a period from July, 1908, to July, 1909. It has been drawn up under the direction of the consulting staff by the medical superintendent, Dr. N. D. Bardswell, aided by the senior assistant medical officer, Dr. James D. Macfie, the pathological portion having been contributed by Dr. J. A. D. Radcliffe. The clinical results obtained were on the whole satisfactory. 72 patients were admitted with incipient disease; in these, arrest occurred in 49 instances, 15 patients were "much improved," 5 "improved," and in 3 the condition was stationary. 121 patients were admitted with a "moderate" extent of disease; in these, arrest occurred in 16 instances, 52 patients were "much improved," 30 "improved," in 15 the condition was stationary, and 8 became worse. 87 patients were admitted with advanced disease; in these there was no instance of arrest; 14 patients were "much improved," 31 "improved," in 23 the condition was stationary, 17 became worse, and 2 died. A considerable amount of interesting work was carried out in the laboratory, especially in regard to secondary infections, and some patients were treated by vaccines made from the organisms isolated from the sputum; the numbers, however, are as yet too few to allow any definite conclusions to be drawn from the results. Several attempts were made to ascertain the presence of tubercle bacilli in the peripheral circulation; the technique adopted is fully described. 16 cases were examined. Of these, 14 were undoubted cases of pulmonary tuberculosis, bacilli having been found in the sputum. One was a very early case without sputum and with doubtful physical signs, but in which von Pirquet's cutaneous reaction was well marked, and in which the opsonic index to tubercle was found to be below normal on three occasions in succession; the other was within normal limits, and the von Pirquet test remained negative. Of the 14 undoubted cases, "acid-fast" bacilli having the morphological appearance of tubercle were found in each case. In the doubtful cases such organisms were not found. It will thus be seen that in addition to the therapeutical advantages offered to patients who seek treatment at the sanatorium useful scientific work is being conducted, thus carrying out the objects for which the sanatorium was founded.

THE SEWERAGE OF TIVERTON.—A Local Government Board inquiry was held at Tiverton, on June 1st, with regard to the application of the town council for sanction to borrow £2000 for works of sewerage and sewage disposal.

THE MEDICAL GOLFING SOCIETY.—This society held its annual tournament on June 2nd at Burnham Beeches by kind invitation of Burnham Beeches Golf Club. The "Henry Morris" challenge cup and the Medical Golfing Society's gold medal were tied for by H. A. Seagrove (12) and J. C. Briscoe (15) with 4 up, H. A. Seagrove taking the first prize in Class I. and J. C. Briscoe the first prize in Class II. The second prize in Class I. was tied for by C. M. Anderson (5), C. J. Marsh (10), and E. T. Robinson (10) with 3 up, while that in Class II. was won by W. H. Kelson with 1 up. The prize for best last nine holes in Class I. was tied for by K. Goadby and G. C. Bell, 2 up, and that in Class II. by C. F. Winkfield and Canny Ryall, 2 up. The foursomes sweepstakes resulted in six ties, G. C. Bell and H. H. Brown, F. Juler and L. Paton, C. M. Anderson and J. R. Walker, W. B. Reid and S. B. Christian, C. I. Graham and C. W. M. Hope, and A. S. Cobbledick and G. B. Scott, all being 1 up.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—Announcements have been sent out that the annual meeting of this association will take place at 3 P.M. on Friday, July 1st, in the council chamber of the Town-hall of the county borough of Halifax, in accordance with the notice already published in these columns. The report of the council for 1909–10 is distributed at the same time and consists mainly of the details of the steps taken by the executive to secure, in the present unsettled state of Poor-law matters, some consensus of opinion from Poor-law medical officers as to the recommendations contained in the recent report or reports of the Royal Commissioners on the Poor-law. 3300 circulars were sent out, and the report contains the answers received, tabulated in accordance with an analysis made by Dr. Major Greenwood and Mr. A. Withers Green, and already published in THE LANCET (see THE LANCET, May 7th, p. 1292). Guided by these answers, the council of the association has framed resolutions, to be submitted to the general meeting at Halifax, protesting against a "break-up" of the present Poor-law system, against indiscriminate medical relief, and against amalgamation of the Poor-law and sanitary medical services, but advocating the retention of the system of "part-time" medical officers. If these resolutions are carried at the Halifax meeting they will come up again for confirmation at a general meeting to be held in London on Friday, July 29th, in connexion with the other meetings of the British Medical Association.

THE CORONERS' SOCIETY.—The annual dinner of the Coroners' Society of England and Wales was held at the Holborn Restaurant, London, on June 2nd, the President, Sir Luke White, M.P., being in the chair. Among the distinguished members and guests present were Sir John Tweedy, the Mayor of Holborn, Dr. W. Wynn Westcott, Mr. J. C. Malcolm, and Mr. H. E. Robinson, past presidents of the society, Sir Thomas Bramsdon and Mr. Luxmoore Drew (vice-presidents), Alderman Pond, J.P., Mr. J. R. Roberts (president of the Justices Clerks' Society), Dr. F. J. Waldo, Dr. W. H. Willcox, Mr. A. Banerji, Mr. Peter Byrne, Mr. P. Foster, M.P., Mr. Henry Rutherford, and Mr. Walter Schröder, the honorary secretary. The loyal toasts having been duly honoured, Sir John Tweedy proposed "The Coroners' Society." He referred to the fact that the office of coroner represented one of the oldest elements in the constitution, probably dating from the ninth century. The Coroners' Society dated back some 50 years, and the excellent work it had done was more than sufficient justification for its existence. As a representative of the medical profession, he was happy to say that the relations between that profession and coroners were almost invariably harmonious. Coroners freely acknowledged the debt of gratitude they owed to the medical profession, and medical men were grateful for the courtesy and help they received from coroners. Sir Luke White, in reply, also congratulated the society that little

difference of opinion existed between coroners and medical men. The report of the Departmental Committee on Coroners' Law and Inquests was an exceedingly valuable document. There was great need of legislation, and he hoped there would be legislation soon. Changes in the directions indicated by the committee would promote alike the interests of the society, coroners, and the community. Mr. Luxmoore Drew proposed "The Guests," to which Mr. Banerji, Mr. Roberts, Mr. Byrne, and Dr. Willcox replied.

BOOKS, ETC., RECEIVED.

AMERICAN CLIMATOLOGICAL ASSOCIATION (Secretary: Dr. Guy Hinsdale, Hot Springs, Virginia, U.S.A.)
Transactions of the American Climatological Association. For the Year 1909. Volume XXV. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BINGHAM, S. O., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Alfreton District of the county of Derby.

DONALDSON, ROBERT, M.B., Ch.B., F.R.C.S. Edin., has been appointed Junior Demonstrator in Pathology at the University of Sheffield.

EVANS, D. GORDON, M.B., B.S. Lond., has been appointed House Physician at the Mount Vernon Hospital, Hampstead.

FOX, C. TILBURY, M.R.C.S., L.R.C.P. Lond., has been appointed Junior Medical Officer to the Ashford Cottage Hospital.

MCDONAGH, J. E. R., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at the London Lock Hospital.

MORTIMER, WILLIAM GRADDON, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator for the South Molton District by the South Molton (Devon) Board of Guardians.

PACKE, G. G., M.B. Cantab., L.D.S.R.C.S., has been appointed Dental Surgeon to the Evelina Hospital for Sick Children.

ROBERTS, W. EDGAR, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the South Devon and East Cornwall Hospital, Plymouth.

ROWELL, J. G., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the West Huddersfield District of the county of York.

SEAL, PHILIP HENRY, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Filleigh, Bucklands, and Charles District by the South Molton (Devon) Board of Guardians.

WALKER, CYRIL HUTCHINSON, M.B. Cantab., F.R.C.S., has been re-appointed Ophthalmic Surgeon to the Bristol General Hospital.

WATSON, J. K., M.D. Edin., has been appointed Medical Officer to the Post Office, Witney; Certifying Factory Surgeon to the Witney District; and Assistant Medical Inspector to the Oxford Education Committee.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon. Salary £75 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing. Each for six months.

BATH, ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and washing.

BENENDEN, KENT, NATIONAL SANATORIUM.—Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and washing.

BEVERLEY, EAST RIDING LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.

BIRMINGHAM GENERAL HOSPITAL.—Resident Surgical Officer. Salary £100 per annum, with residence, board, and washing.

BIRMINGHAM, QUEEN'S HOSPITAL.—House Physician for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

BIRMINGHAM, WARWICKSHIRE COUNTY COUNCIL.—Assistant County Medical Officer of Health. Salary £250 per annum.

BRADFORD ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, &c.

BROOKWOOD, NEAR WOKING, SURREY COUNTY LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon; also House Surgeon for Ophthalmic and Ear and Throat Departments, each for six months. Salary £30, with board, residence, and laundry.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance. Also Honorary Aural Surgeon.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—House Physician. Salary at rate of £60 per annum, with board, residence, and washing.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HEREFORD COUNTY AND CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £120 per annum, with board, apartments, laundry, &c.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician and Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board and residence.

HULL, ROYAL INFIRMARY.—Casualty House Surgeon for six months. Salary at rate of £60 per annum, with board and lodging.

INDIAN MEDICAL SERVICE, India Office, London.—Fifteen Commissions in His Majesty's Indian Medical Service.

LEEDS HOSPITAL FOR WOMEN AND CHILDREN.—House Surgeon for seven months. Salary at rate of £50 per annum, with board.

LEICESTER BOROUGH ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

LINCOLN COUNTY HOSPITAL.—Senior House Surgeon, unmarried. Salary £125 per annum, with board, lodging, and washing. Also Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—House Surgeon. Salary £80 per annum, with board, rooms, and laundry.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon for six months. Salary £75 per annum.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Third Resident Medical Officer. Salary £60 per annum, with board, residence, and laundry.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £100 per annum, with board, apartments, and washing.
NOTTINGHAM CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Two House Surgeons and Two House Physicians for six months. Salary at rate of £80 per annum, with board, residence, and washing, in each case. Also Assistant Physician.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Junior Obstetric Assistant and Clinical Assistants (all females.)
ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.
SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, attendance, and rations.
SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician, unmarried. Salary £50 each per annum, with board, lodging, and washing.
SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.
STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.
TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.
TEIGNMOUTH HOSPITAL, S. DEVON.—House Surgeon. Salary £80 per annum, with board, residence, and laundry.
VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board lodging, and washing.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £30, with board, lodging, and laundry.
WAKEFIELD, WEST RIDING ASYLUM.—Locum Tenens Assistant Medical Officer. Salary £3 3*s.* per week, with apartments and board.
WEST BROMWICH DISTRICT HOSPITAL.—Assistant Resident House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL—House Surgeon.
WORKSOP DISPENSARY AND VICTORIA HOSPITAL.—Medical Officer and House Surgeon. Salary £150 per annum, with rooms, furniture, coals, gas, &c,

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Glenarm, in the county of Antrim; at Southam, in the county of Warwick; and at Rathfriland, in the county of Down.

Births, Marriages, and Deaths.

BIRTHS.

MORE.—On June 4th, at Rothwell, near Kettering, the wife of John More, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., of a son.

MARRIAGES.

CLARIDGE—BURTON.—On Wednesday, June 1st, at Christ Church Eaton, Norwich, George Percival Charles Claridge, M.B., B.S. Lond., to Grace Margaret, second daughter of Mr. and Mrs. George J. Burton of Norwich.
CRAWFORD—CHAVANNES.—At Richmond Terrace Chapel, Bradford, on June 1st, by the Rev. George Frayn, John C. Crawford, M.B., C.M., of Keighley, to Marguerite, elder daughter of Mons. Edouard Chavannes, Civil Engineer, Lausanne. At home, 3, Haincliffe-road, Ingrow, Keighley, July 5th.
MCKAY—MOREY.—On June 1st, at St. Mary's, Wimbledon, Joseph Boyle McKay, M.D., M.Ch., &c., to Florence Eveline, only daughter of the late Henry W. Morey and of Mrs. Morey.
STEWART—WENDOVER.—On June 2nd, by special licence, at St. John's Church, Walmer, Port Elizabeth, Cape Colony, Andrew Stewart, M.B., Ch.B. Glasg., to Dorothy Kathleen Mary, second daughter of Edwin Wendover, of Braughing, Herts, England.

DEATHS.

BLACKWELL.—On May 31st, at Rock House, Hastings, Elizabteh Blackwell, M.D., in her 90th year.
MURRAY.—On June 4th, at Edinburgh, John Murray, Brigade Surgeon, late H.M. Madras Army, aged 75 years.
PEAKE.—On June 5th, at Homefield, Platt's-lane, Hampstead, William Harland Peake, M.D., B.S., aged 40 years.
SPENCER.—On May 27th, at 8, Osberton-road, Oxford, William Henry Spencer, M.A., M.D. Cantab., M.R.C.P., F.L.S., Consulting, late Senior, Physician of the Bristol Royal Infirmary, late Lecturer on Medicine at Bristol University Medical School, aged 72 years.
STARTIN.—On June 2nd, at Broadstairs, James Startin, M.R.C.S., aged 59 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CHINESE PORK.

DURING the year 1909 several questions were asked of the President of the Local Government Board in the House of Commons as to whether the carcasses of pigs imported into this country from China were wholesome. As a result of these questions an inquiry was instigated, and in the report of the Public Health Department recently published, Dr. W. Collingridge, the medical officer of health of the City of London, makes an important statement in reference to this matter. In July, 1909, a vessel from China arrived at the Royal Albert Docks with 4663 frozen pigs on board. When the carcasses had been thawed and examined it was found that 391 were unfit for food, this notwithstanding the fact that they bore labels (attached at the port of shipment) to the effect that the meat had been "medically examined and certified free from disease." Dr. Collingridge states that the glands had not been examined, and he concludes therefore that the inspection must have been of a most perfunctory nature. On communication with the medical man whose signature appears on these labels, Dr. Collingridge found that he did not act in any official capacity, but merely as a private examiner on behalf of the English importers. Dr. Collingridge has received an assurance that the examination at the Chinese port will be more exactly carried out in the future. In the report attention is drawn to the magnitude of the task of examining so many carcasses, and it is stated that in the event of an increase in this trade with China the examination cannot be adequately conducted on the lines of the present system. The British Consul at Hankow has given his assurance that pigs of the wild variety, which live as scavengers in the public streets of the Chinese towns, are not exported to England, but that the animals which are sent here are raised on well-managed pig-farms in the district between Tungling Lake and Lokow.

THE COST OF THE MOTOR-CAR.

To the Editor of THE LANCET.

SIR,—Last year I sent you a note, which you inserted in your issue of May 8th, 1909, giving particulars of the cost of running my 12-h.p. "Star" car. The second year's figures make an interesting comparison with those of the first year, and give evidence of the consistent performance and reliability of the car. I have never been stopped on the road, except for tyre trouble. The figures for this year are:—

	£.	s.	d.
Petrol	14	2	2
Tyres	13	4	7
Repairs and replacements (including engine overhaul £6)	11	1	6
Oil, grease, and sundries	2	12	4
Insurance and licence	13	16	6
	54	17	1

The mileage for the 12 months was 5785. Last year's total cost was £48 17*s.* 7*d.* for 6045 miles. This year's cost has been practically the same, the extra £6 being for an overhaul of the engine after having done 10,000 miles. I am, Sir, yours faithfully,

Liverpool, June 2nd, 1910. J. SAFFLEY, M.B. Edin.

THE POST OF MATRON AT ST. BARTHOLOMEW'S HOSPITAL.

CONSIDERABLE dissatisfaction exists among the nurses at St. Bartholomew's Hospital in consequence of the appointment of an assistant matron from the London Hospital as successor to Miss Isla Stewart, the late matron of St. Bartholomew's Hospital. On June 6th, in the rooms of the Medical Society of London, Chandos-street, W., a meeting of "trained nurses and others interested in the efficient care of the sick" was presided over by Miss Maud Banfield, when a vigorous protest was made against the appointment. Among a number of letters of sympathy which were read by the honorary secretary was one from Dr. Leonard C. T. Dobson who wrote: "I can conceive of no step more calculated to damage the prestige of the St. Bartholomew's nurses in the eyes of the public than this one, or to undermine the feelings of loyalty of the Bart.'s staff to their own institution." In another letter Dr. Richard J. Reece said: "On the face of it, and unless adequate explanation is forthcoming, it seems to me that a grave slight has been passed on a number of ladies who have in no way deserved such treatment." On the proposal of Miss Kingsford, seconded by Mrs. Stabb, a long resolution calling for a public inquiry was carried unanimously. This resolution included the following: "This meeting furthermore is strongly of opinion that the said public inquiry should also investigate the condition of the nurses' home of St. Bartholomew's Hospital, which has for years been condemned as insufficient for the accommodation of the nursing staff, as insanitary,

and as a death-trap in case of fire for the nurses who occupy the antiquated houses which compose the home." Mrs. Bedford Fenwick expressed her belief that no woman since Miss Florence Nightingale had done more for the improvement of nursing than Miss Isla Stewart. She considered the action of the authorities almost a crime and thought that the challenge thrown down by autocratic trustees of charitable funds should be met at once by a demand for immediate legislation to protect nurses from coercion and persecution. Before the conclusion of the meeting, which was characterised by great animation throughout the proceedings, it was decided to send copies of the resolution to His Majesty the King, as President of St. Bartholomew's Hospital, to every governor, and to the members of both Houses of Parliament, praying "that justice shall be done to the memory of a noble woman and to the body of women trained under her direction."

THE "NONGAR" PIPE.

INNUMERABLE as are the devices which are directed to condensing the tar oils and bases of tobacco smoke in the pipe before they reach the mouth of the consumer, there would appear to be room for one more in the "Nongar" pipe on the ground chiefly of its simplicity of construction and action. There is a lateral space under the bowl into which the mouth-piece projects. There is a free space round this projection, so that the drainage of condensed oils down the mouth-piece is avoided, and, further, this condensing chamber is lined with aluminium which prevents the oils soaking into the wood of the bowl. The result is satisfactory so long as care is taken to withdraw the condensed oils and water as they accumulate. The pipe, which bears no evidence in external appearance of any special construction, was submitted to us by the "Nongar" Pipe Company of Strand-road, Liverpool.

THE MEDICAL LAW-STUDENT.

To the Editor of THE LANCET.

SIR,—Would you or some of your correspondents kindly answer the following questions through your columns:—1. Is it quite possible for a medical man to read for the Bar with any prospective measure of success in his spare time? 2. Should it be done with the help of a "correspondence coach"?

Any experiences of your subscribers or other medical men who have done this would be appreciated by

Yours faithfully,

June 5th, 1910. LEGAL.

*** Our correspondent may have noticed by announcements in our columns that many of his medical colleagues have read for the Bar successfully while carrying out their medical engagements, but obviously the ease with which this can be done depends first on the attainments of the man, and, secondly, on the amount of his spare time.—ED. L.

DISTILLERY WASTE.

A VERY serious source of pollution to certain of the Scotch rivers is the offensive residue obtained in the manufacture of whisky, and it has only recently been demonstrated on a practical basis that a method of bacteriological purification will successfully deal with this nuisance. The first distillers to adopt with success the methods of purification recommended by the Royal Commission on Sewage Disposal in its sixth report are the proprietors of the Craigellachie Distillery, one of the White Horse distilleries. These distilleries were recently visited by some representatives of the Commission, who expressed great satisfaction with the results obtained. The standard of purification attained is evidently high, since the final effluent produced by this bacteriological process of purification is such that salmon ova have been successfully hatched in it and fish life is abundantly supported. These experiments in a public health matter of great importance are decidedly interesting.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Walter G. Spencer, Jonathan Hutchinson), in the Large Theatre, Medical School, University College, W.C.: at 5.30 P.M.

Discussion:

On the Present Position of the Treatment of Syphilis. (Second Meeting.)

WEDNESDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (Fifth Meeting). Re-opened by Mr. Deane Butcher, and continued by Dr. Lewis Jones, Dr. L. S. Dudgeon, Dr. David Lawson, Dr. Crace-Calvert, Mr. Leonard Noon, Dr. Wm. Parry Morgan, Dr. J. C. MacWatters.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—E. G. Graham Little, H. G. Adamson) at 11, Chandos-street, W.: at 5 P.M. Demonstration of Cases.

ROYAL SOCIETY.

THURSDAY.—Ordinary Meeting.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

FRIDAY.—3 P.M., Annual General Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Dr. F. W. Andrewes: The Behaviour of the Leucocytes in Infection and Immunity.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. G. Adamson: Clinique (Skin). 5.15 P.M., Lecture:—Sir John Broadbent, Bart.: Malignant Endocarditis.

TUESDAY.—4 P.M., Dr. W. Ewart: Clinique (Medical). 5.15 P.M. Lecture:—Mr. A. Carless: Malignant Disease of Bone (lantern illustrations).

WEDNESDAY.—4 P.M., Mr. J. P. Freyer: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. W. Stuart-Low: Malignant Disease of the Nasal Passages, its Pathology, Diagnosis, and Treatment.

THURSDAY.—4 P.M., Dr. C. T. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. Oliver (Harrogate): Some Bedside Clinical Methods with Demonstrations and Examples.

FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. B. Harman: Acute Iritis.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 11.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Pritchard: Clinical Pathology.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Morton: X Ray Examination of Urinary System.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture III.)

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstrations of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with Cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles). 4.30 P.M., Lecture-Demonstration:—Mr. A. de Prenderville: Anæsthetic Dangers and How to Avoid Them.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie). Demonstration (at the Northwood Sanatorium):—Dr. A. J. Whiting: The Diagnosis and Treatment of Early Pulmonary Tuberculosis.

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.
MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Mr. R. Lake: Operation for Acute Mastoid Disease.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4 P.M., Special Lecture:—Mr. J. Taylor: Some Clinical and Pathological Aspects of Nervous Disease.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.
THURSDAY.—4 P.M., Lecture:—Mr. Waugh: Acute and Chronic Inflammatory Lesions of Bone.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.
WEDNESDAY.—4 P.M., Lecture:—Dr. Habershon: Mitral Stenosis.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.
TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. A. Wylie: Larynx.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.
TUESDAY.—3.30 P.M., Clinical Lecture:—Sir William Gowers: Vertigo.
WEDNESDAY.—5 P.M., Demonstration:—Mr. P. Sargent: Surgery of the Nervous System—Cranial Injuries.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. E. F. Buzzard: Cases. 5 P.M., Demonstration:—Mr. P. Sargent: Surgery of the Nervous System—Surgical Treatment of Lesions of the Spinal Cord.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C. (In the Lecture Room of the Institute).
WEDNESDAY.—6 P.M., Brevet Lieut.-Colonel Sir W. B. Leishman: Anti-Typhoid Inoculation. (Harben Lecture.)

MANCHESTER ROYAL INFIRMARY.
TUESDAY AND THURSDAY.—4.30–5.30 P.M., Honorary Staff: Post-Graduate Clinical Demonstration (Medical, Surgical, and Special Departments).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (18th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Dr. B. Anningson, Cambridge; Messrs. E. Archer and Co., Malvern; *American Journal of Clinical Medicine*, Chicago, Manager of; Dr. Lewis H. Adler, jun., Philadelphia; Anglo-American Pharmaceutical Co., Croydon; *Army and Navy Gazette*, Lond.; Association of Patent Experts, Lond.; Dr. James F. Allen, Pietermaritzburg.

B.—Messrs. Blundell and Rigby, Lond.; Mr. J. Billmeier, Lond.; Birmingham General Hospital, Secretary of; Mr. A. Bishop, Lond.; Dr. M. Blok, Lond.; Dr. F. E. Batten, Lond.; Dr. J. S. Bolton, Nottingham; Mr. W. G. Burcombe, Lincoln; Messrs. Battle and Co., Neuilly; Bury Infirmary, Hon. Secretary of; Messrs. C. Barker and Sons, Lond.; Messrs. A. Burbridge and Co., Lond.; Messrs. Boulton and Paul, Norwich; Messrs. Burgoyne, Burbidges, and Co., Lond.; Mr. S. H. Benson, Lond.; Bristol Myers Co., Brooklyn, U.S.A.; Beable's Advertising Agency, Lond.; British Union for the Abolition of Vivisection, Lond., Secretary of; Mr. J. A. Barnes, Lond.; Mr. Charles Budd, Shanghai.

C.—Mr. F. W. Clarke, Chorlton-cum-Hardy; Croydon Corporation, Clerk to the; Camberwell Guardians, Lond., Clerk to the; Coventry and Warwickshire Hospital, Secretary of; Messrs. J. and A. Churchill, Lond.; Dr. F. Calot, Berck-Plage; Dr. H. C. Cameron, Lond.; Messrs. Carfax and Co., Lond.; Cardiff Infirmary, Secretary of; Mr. H. Ley Clark, Lond.; Messrs. A. H. Cox and Co., Brighton; Central News, Lond., Manager of; Mr. D. Cotes-Preedy, Gerrard's Cross.

D.—Mr. R. W. Doyne, Lond.; Mr. R. C. Davies, Liverpool; Mr. E. Q. Derriman, Lond.; Dr. C. A. A. Dighton, Scarborough; Messrs. Durand, Bennett and Co., Lond.; Messrs. F. Davidson and Co., Lond.; Mr. A. E. Duchesne, Lond.; Major C. Donovan, I.M.S., Madras.

E.—Dr. C. Ewart, Lond.

F.—Dr. C. E. Finlay, Havana; Mr. P. V. Fry, Sowerby Bridge; Mr. T. Jefferson Faulder, Lond.; Dr. A. Mearns Fraser, Portsmouth.

G.—Dr. R. Martin Gil, Malaga; Mr. David M. Greig, Dundee; Dr. C. C. Guthrie, Pittsburg; General Medical Council, Lond., Registrar of; Glasgow District Lunacy Board, Gartcosh, Clerk to the; Gloucestershire Royal Infirmary, Gloucester, Secretary of.

H.—Dr. F. Hare, Beckenham; Mr. W. J. Harris, Cambridge; Mr. A. T. Harrison, Sherburn; Hull Royal Infirmary, Secretary of; Hereford County and City Asylum, Clerk to the; Dr. D. Fraser Harris, Birmingham; Messrs. Hooper and Batty, Lond.; Mr. N. Bishop Harman, Lond.; Hove Borough Education Committee, Secretary of.

I.—India Rubber, Gutta Percha, and Telegraph Works Co., Lond.

J.—Mr. W. H. Johnston, Dublin; Dr. J. Johnston, Bolton.

K.—Messrs. R. A. Knight and Co., Lond.; K. L. S.; Kidderminster Pencil Co., Manager of; Messrs. Krohne and Sesemann, Lond.; Dr. A. M. Kennedy, Glasgow; Mr. Shridhar V. Ketkar, Ithaca.

L.—Mr. H. K. Lewis, Lond.; Leeds Hospital for Women and Children, Secretary of; Mr. E. Lakovski, Lond.; *Liberty*, Lond.; Brevet Lieutenant-Colonel Sir W. B. Leishman, R.A.M.C., Lond.; Liverpool Eye and Ear Infirmary, Hon. Secretary of; Mrs. Langworthy, Lond.; Messrs. Lee and Nightingale, Liverpool; Mr. T. P. Legg, Lond.; Mr. E. Lewis, Burnley.

M.—Mr. R. J. Macredy, Lond.; Mr. J. Wallace Milne, Aberdeen; Messrs. Maple and Co., Lond.; Dr. J. MacEwen, Glasgow; Maltine Manufacturing Co., Lond.; *Medical Review*, Lond., Manager of; Medical Graduates' College and Polyclinic, Lond.; Metropolitan Asylums Board, Lond., Clerk to the; Mysore Government, Bangalore, Senior Surgeon to; Mr. J. F. Mackenzie, Edinburgh; Mr. P. Lockhart Mummery, Lond.; Dr. B. Melland, Altrincham; Sir H. Morris, Bart., Hythe; Dr. S. G. Moore, Huddersfield.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Natural Food Reform Association, Lond.; Nottingham Children's Hospital, Secretary of; Newport and Monmouthshire Hospital, Secretary of; Nottingham General Hospital, Secretary of; Messrs. D. Van Nostrand Co., New York; Nottingham City Asylum, Clerk to the; National Sanatorium Association, Benenden, Secretary of.

O.—Mr. C. Jocelyn O'Helier, Lond.; Professor Dr. A. Oppel, Halle.

P.—Dr. W. A. Potts, Edgbaston; Messrs. Parkin, Ness, and Co., Darlington; Mr. N. Porter, Lond.; Dr. Pierre's Eau Dentifrice, Lond., Manager of; *Phonographic Record*, Lond.; Mr. Frank T. Paul, Liverpool.

Q.—Queen's Hospital, Birmingham, Secretary of.

R.—Royal Meteorological Society, Lond.; Royal Society, Lond.; Messrs. Reynolds and Branson, Leeds; Royal Society of Medicine, Lond., Secretary of; Messrs. Reitmeyer and Co., Lond.; Royal National Orthopædic Hospital, Lond., Secretary of; Royal Hampshire County Hospital, Winchester, Secretary of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

A Lecture
ON
FOREIGN BODIES IN THE AIR-PASSAGES.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton,

BY RICKMAN JOHN GODLEE, M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE HOSPITAL.

GENTLEMEN,—It is said that the class of cases now treated at this hospital is not quite the same as it used to be in my time, and that my successor does not meet with the same variety that came under my care in the days in which any disease that could possibly be considered to be included within the walls of the thorax was considered to be suitable for treatment; and even that definition was allowed some freedom of interpretation. I was, therefore, rather puzzled when asked to deliver one of this course of lectures as to what subject would be thought to be a proper one on which anything new could be said, and probably that which I have chosen is not often illustrated here, unless it may be when the presence of a foreign body has not been suspected, or when one has remained so long in the lung before its removal that serious, if not permanent, damage has been produced.

The subject is one, however, in which great advances have been made within recent years, and although these advances have not come so much from general surgeons as from the laryngologists, they are of great importance for both surgeons and physicians, and perhaps demand the most serious attention of all from general practitioners, with whom it often rests, either by taking prompt action or by interposing delay, to afford their patients quick relief or to allow them to drift into a condition in which no medical or surgical aid is of much use.

This point needs emphasising, because it is well known, as was pointed ont in my lectures on this subject at this hospital in 1896, that when a foreign body has passed into one of the main bronchi it may for a time cause such slight symptoms that the patient and the medical man can hardly believe it to be really there. It is true in my experience of such a body as a collar stud, a piece of bone, an ear of barley grass, a pin two inches long, or the end of a vulcanite tracheotomy tube. There may, indeed, be complete absence of physical signs in the case of such an object as a pin, or if it be a smooth thing like a bead there may be no departure from the normal physical signs except such as are due to a slight deficiency of entry of air into that part of the lung which corresponds to the partially obstructed bronchus. If, however, it be a piece of bone or a piece of meat, decomposition at once sets in, and then the mischief which has started in the lung may be very serious indeed, and of a progressive character.

CLASSIFICATION OF FOREIGN BODIES.

It has been suggested that such foreign bodies as enter the air-passages should be divided into hard and soft, which is a useful enough, though by no means an accurate, classification. It is useful in cases where immediate removal is to be attempted. If a hard object can be caught by the forceps, and the forceps hold, out it comes if it does not break, but a soft object may be nibbled at again and again without materially diminishing its dimensions. But there are other classifications that might equally well be made; for example, into living and dead. We have all heard of the leech and the round worm that have made their way into the trachea, and I almost envy the emotion that will be experienced by the first observer who sees such an animal or the grub of a dipterous insect through the bronchoscope. Seeds such as those of peas and grass are also, of course, alive, and may swell and perhaps germinate, and these are the foreign bodies that carry in along with them other forms of life, such as the organisms that produce actinomycosis, or the various forms of mould which, when they have gained a footing in the lung, produce such frightful ravages. If one were to stretch the definition of foreign bodies and include amongst them substances like iron filings or minute fragments of stone or coal, it is clear that a great many more diseases would have to be discussed than naturally find a place in this lecture.

Again, there are some foreign bodies which, when once they have come to a standstill, do not shift their position, such as a tooth sitting astride on the septum between two separating bronchi, whilst there are others which though dead have a proper motion, which may conduct them any distance and in any direction. Needles will find their way into the heart or into the distant parts of the body, and blades of awned grass or corn, which the unwary are so fond of putting into the mouths, start on their travels almost like living creatures. This specimen was extracted from the back of a small child who was supposed to have had whooping-cough, though the nurse knew that a piece of grass had been "swallowed." The medical man thought the emerging grass was the core of a boil, and was rather astonished when the whole ear was extracted by his forceps.

MOVEMENTS OF THE BRONCHI.

It may be asked why such objects should make these journeys at all? We are so unconscious of any of the movements inside our own bodies that it is difficult to imagine the churning and pulsating and elongation and shortening which are constantly taking place throughout our economies. Moreover, if we start with the idea that the root is a very fixed part of the lung, it might be thought that a foreign body which had once reached this haven would remain quietly at anchor there, but radiography and the bronchoscope have upset all these notions, and we can now submit to the scrutiny of the eye questions which previously were only matters of reasoning or surmise.

Dr. Arthur Keith has thought and written much on the movements that take place within the chest, and it is from his writings and demonstrations and from conversations with him, as well as my own observations, that the following statements are founded.

I am not now concerned with the differences in the movement that depend upon the age or sex of the individual, though they are important; but, speaking generally, it may be said that the only fixed part of the lung is the true apex, that is, the part that corresponds to the neck of the first rib. The central tendon of the diaphragm is not, as we used to think, almost stationary, but moves downwards about 10 mm. (2-5ths inch) in ordinary inspiration, and 30 mm. (1¼ inches) in deep inspiration, as is easily seen on the radiographic screen. It also moves forwards nearly to the same extent as the lower part of the sternum moves from the spine, this movement being accounted for by the shortness of the muscular fibres in front, and by their length and abundance behind. Both the upward and downward and the antero-posterior movements are accompanied by corresponding movements of the heart and of the roots of the lungs, though as the position and the shape of the heart vary, and as the pericardium is not a rigid sac, the upward and downward movements of the roots of the lungs are not so extensive as the movement in these directions of the central tendon of the diaphragm. The antero-posterior movements are also less than those of the sternum. It is interesting to remember that the two pleuræ touch in front of the heart, and often also behind it; there is, in fact, both in front and behind, a sort of meso-pericardium, and these two folds of pleura are extensible, and so allow during inspiration of the thickening of the thin anterior borders of the lungs and of the inflation of their thick posterior parts. It has been pointed out how, if the chest be examined through the screen obliquely from, say, the left front to the right back, the shadow of the heart is continuous with that of the spine during expiration, whereas during inspiration a broad band of transparency intervenes between the two shadows corresponding to the fully inflated two lungs; and I am able to show you some beautiful skiagrams kindly lent me by Mr. Schall, in which, in a direct side-to-side view, the same band of light appears between the heart and the spine during inspiration. They afford a very clear demonstration not only of the fact but of the very considerable amount of this movement.

But besides this general movement of the roots of the lungs, there is another special movement—i.e., a movement of the bronchi. For as the upper part of the lung is more fixed than the lower, there is some resistance to the traction downwards of the lower part. It might have been thought that the result would be that the

angle between the two main bronchi would have been diminished. But there is another force which modifies this angle—namely, the inflation of the masses of lung which are situated between them and the heart, and which increase considerably in volume during the act of inspiration. This would tend to widen the angle, and I am told by Dr. Keith that he believes that the angle is as a matter of fact actually widened during inspiration. I have tried to see some movement of this kind in looking through the bronchoscope, but have not been able to detect it. I can imagine it might be very effectual in aiding the movements of the ear of corn.

As we are now only occupied with the roots of the lungs it will not do to enter into a discussion of the particulur movements of the various parts of that organ, but I have been struck with Dr. Keith's observations that, again speaking generally, the direction of the bronchi indicates the direction in which that part of the lung moves. It suggests that perhaps one use of the muscular fibres in the bronchi is to shorten up these tubes after they have been extended during inspiration, though it is believed that the principal action of these muscles is to diminish the calibre of the bronchi. No shortening or lengthening can be seen by direct observation. To the eye the beautiful alternative red and white bands do not appear to change their respective widths, and indeed it was scarcely to be expected that any change would be actually visible, although one knows that with every breath each tube is being first lengthened and then shortened to a certain extent.

I do not know that all the movements that are caused by the simple act of breathing have now been mentioned, but it is clear that during coughing, sneezing, yawning, and vomiting they are all exaggerated. In the act of coughing I have also seen a most surprising sight on one occasion, when looking at the orifice of a secondary bronchus after manipulation for the extraction of a foreign body had been some time in progress. The patient made an expulsive effort, and I saw this orifice close completely. I do not say that this was effected solely by the contraction of the bronchial musculature, because there are more or less incompressible things in the neighbourhood that by their pressure might help to close it, but I think it is a most suggestive fact for those who are studying what occurs in spasmodic asthma, and that it helps to explain the sudden relief to the wheeze that accompanies a common bronchitis of the larger tubes when such a substance as menthol is inhaled.

Respiration is not, however, the only factor in the movements of the main bronchi. Every beat of the heart makes the left bronchus move almost vertically up and down $\frac{1}{8}$th inch or more. This may be actually seen. The direction in which the right bronchus moves I do not know, but presumably it is more inwards and outwards. It is almost dreadful to see the cardiac and arterial movements when examining with the bronchoscope, for the main bronchi are, like Gobbo's conscience, literally "hanging about the neck of the heart," and it is practically certain that the smaller bronchi have a similar, though smaller, movement transmitted to them by their accompanying arteries.

ASEPTIC AND SEPTIC FOREIGN BODIES.

The automatic movement of the ear of barley grass has led us a long way, but I think there is no need to go further and to ask if deglutition has any effect on the movements of the bronchi or to refer to the general movements of the body. Enough has been said to account for the journey, not only into the smaller bronchi, but to the periphery of the body. And so, returning to the question of the classification of foreign bodies, we must consider what is, perhaps, the most important of all, namely, of those which may be called aseptic, from those which are either septic at the time of introduction, or which quickly decompose or form favourable niduses for the growth of micro-organisms. Amongst the latter are included pieces of flesh or other kinds of food, which may gradually become disintegrated; and worse than these, fragments of bone or cloth or cotton wool, which are practically indestructible. I have seen so many cases of bronchiectasis and pulmonary abscess following at a short interval on some nasal operation, as to make its almost certain that something like a fragment of an adenoid growth or some morsel of cotton wool which has been inspired at the time, has been the starting-point of the disease, and I therefore have never adopted the semi-erect position for these operations. The risk of such an occurrence must surely be less when the head is hanging over the table, and I therefore commend this consideration to those who are specially engaged in this line of practice.

FOREIGN BODY IMPACTED IN THE TRACHEA.

A foreign body which has entered the larynx may, of course, stick at the rima glottidis, but unless it is very small and sharp like a fish bone, or a needle, it is not likely to remain there long, the spasmodic cough which ensues leading either to its immediate expulsion or to rapid suffocation of the patient. If neither of these events occur there should with modern methods be no great difficulty in its extraction. But sometimes it may lodge immediately below the vocal cords. This may mean that it has at first passed more deeply and then by expiratory efforts been driven back against the glottis from below and stuck there. I have seen at least two such cases; one was that of a sharp fragment of shell which I extracted through a tracheotomy wound, and the other was that of a grain of corn which lodged between the thyroid and the cricoid cartilages, and formed an abscess which was opened externally. The subject of this accident was intended for a university career, which, on the appearance of the abscess, he proposed to relinquish because it was thought to be tuberculous.

When one considers the narrowness of the chink between the vocal cords it might have been thought that any object that was small enough to pass the rima glottidis would not have been large enough to stick in the trachea. Such, however, is not the case—plum stones, and even more unlikely things, have been known to run the gauntlet and to have become impacted in the trachea. There is one such specimen in the Museum of the Royal College of Surgeons of England, taken from the body of a lunatic whose death was the immediate consequence of the mishap. I may observe in parenthesis that there are many recorded cases of foreign bodies which have found their way into the air passages of lunatics, as indeed is not very surprising. It would require very prompt action to extract such a body as this before death supervened. And some of the things inspired have been more extraordinary still—screws, long pins, a needle and thread, the tail of a herring, large pieces of meat and vegetables, beans, nails, teeth, the peg of a peg-top, a necktie holder, and a whistle, which caused as strange sounds to be produced in the patient's chest as those which startled the parents of Dickens's "fat boy."

One can imagine many of these sticking in the trachea; but the majority pass lower down and most of them lodge at the end of one or other of the main bronchi, perhaps three-quarters of them in the right bronchus.

FOREIGN BODIES IN THE BRONCHI.

Since the classical observations of Aebey it has been recognised that the reason why most pass into the right side is because the lower end of the trachea after turning slightly to the right becomes almost directly continuous in direction with that of the right bronchus, which is the larger of the two. This is clearly shown in metal casts and also by means of radiograms. After the foreign body has reached the end of the main bronchus, if it is small enough, it may pass in any direction, and although the main bronchus is continued down to the base of the lung with a slight convexity outwards on the right side, and a considerable convexity on the left side, whilst the other tubes are branches, dorsal or ventral from this main trunk, it will not be forgotten that these branches are so large that until Aebey set us right it was the custom to describe the bronchi as dividing and subdividing dichotomously. It is not, therefore, to be expected that such small round bodies as glass beads would always enter that particular one of the smaller bronchi which we recognise from the study of comparative anatomy to be the main stem. It is probable that it could equally easily pass into others which follow pretty nearly the same direction, and this makes the search more difficult and more indefinite.

USE OF X RAYS.

The expectation that a foreign body will be shown by radiography or seen with the screen is often disappointed. If it should be of metal or of glass, it will be apparent; but if of bone or ivory it will most likely be indistinguishable from the ribs, and if of meat or vegetable it stands to reason that it will not show up at all. It is important that radiograms should be stereoscopic, and it is theoretically best that they should be instantaneous and taken at the moment of

full inspiration. If not instantaneous, the image is sure to be blurred, and if not taken in full inspiration the lung will not be as transparent as possible. But there are many difficulties about instantaneous radiography; and so both of these directions may be dispensed with in the case where the object is of easily recognisable shape and opaque to the X rays.

By means of instantaneous radiograms it is now possible to show the course, not of the main bronchi, but of their accompanying vessels. I have the opportunity of exhibiting a number of beautiful skiagrams lent me by Mr. Schall which show these radiating lines. The bronchi themselves cannot cast a shadow in their normal condition; they are mostly made of cartilage which does not obstruct the X rays, and they contain air which has the same property. They, therefore, would only appear in a skiagram as bright lines, and only thus in an imperfectly expanded or collapsed lung. It seems clear, however, that these radiating lines actually depend upon the vessels. What I have just said applies, however, only to healthy bronchi. It does not follow that they will not produce shadows if they are filled with pus.

Much has been written on this subject. The last paper on the so-called "Hilus-Zeichnungen"—"hilus markings"—I have seen is by Eug. Fränkel and Alex. Lorey.[1] These radiating lines appear as unrecognisable blurred streaks in radiograms obtained by a long exposure, and their appearance is often much confused by opacities which depend upon calcareous glands, or perhaps even by glands containing large quantities of carbon. It is well to make oneself familiar with these appearances before committing oneself to an opinion about foreign bodies, and it is wise before making use of the screen to form a clear mental picture of the direction in which the different parts of the lung move. The observer should also make sure that there is no opaque substance on the surface on the body which could possibly be mistaken for something in its interior.

Results of Foreign Bodies in the Bronchi.

The changes produced in the lung and air passages depend, as has been hinted, on the nature of the foreign body and the place where it lodges. I will not dwell upon the result of the impaction of an object in the trachea sufficiently angular to stick there, but not large enough to obstruct the passage of air. It will probably give rise to a constant cough and set up inflammation of the surrounding parts and a descending tracheitis, but even this is not certain.

A sharp object like a long pin may become fixed in one of the main bronchi and cause no symptoms for months (probably longer) except a slight cough and give rise to no physical signs except a few crepitations behind the sternum. A tube like a tracheotomy tube may certainly for some days produce only similar insignificant results, whereas even such a small and rounded object as a collar stud may in a few weeks start such changes in the bronchi and lung as may lead to incurable bronchiectasis. Changes of this nature follow very quickly on the introduction of pieces of bone and other putrescible substances. It is a striking object-lesson to see and to smell a piece of bone that has been inspired only a few days before. In such a case it is generally possible by careful auscultation to determine which bronchus is blocked, as the entry of air is diminished in the corresponding part of the lung. This may be a whole or only part of a lobe or the whole lung. The movements of a corresponding part of the chest are diminished and crepitations may be heard over the affected area. It is not long before the mischief extends to other parts, especially the base of the lung, and in the course of time, if nothing worse happens, bronchiectasis is sure to be established at the base.

I have long made it a rule in cases of unilateral bronchiectasis, especially in children, to make careful inquiries as to the possibility of a foreign body having been inspired. People forget, strange to say, that the accident has happened. Parents and nurses not only forget, but sometimes have never noticed, its occurrence; it has been taken just for a fit of coughing, and no attention has been paid to it. I have known a father, who was a medical man to boot, forget that he was feeding his own child with mulligatawny soup, during which the infant choked on inspiring a piece of bone, and subsequently developed what was supposed to be an empyema. I have also known a boy say nothing about the fact that he had inspired the peg of a peg-top for fear of being punished. So we should never fail to pay the greatest attention to any spontaneous evidence on the part of the patient, for patients are more likely to be right than wrong, and yet there is a tendency to look upon such stories as fairy tales.

If the foreign body be removed or escapes, recovery may be complete if the lung has not been much damaged, but not infrequently the resulting bronchiectasis is permanent, though it is not necessarily progressive, and the patient may live for many years. Some of the most disastrous effects are produced by ears of corn. They may cause pneumonia and acute abscess, and such an abscess may extend into the pleura or through the diaphragm. This is illustrated by a preparation taken from a patient on whom I operated in this hospital for what was at first supposed to be empyema. An object that completely blocks a bronchus may give rise to that condition of collapse and gangrene of a corresponding part of the lung that is recognised as following an obstruction to a bronchus from pressure upon it by a tumour such as an aneurysm.

In considering the remote results of a lodgment of foreign bodies in bronchi, one must not forget the possibility of tubercle being engrafted upon the mischief caused immediately by the accident. Such occurred in the patient from whom this specimen was obtained, of a tooth impacted in a bronchus, who was operated upon in this hospital by Mr. Marshall and myself many times. It should also be added that a recognisable percentage will probably die from cerebral abscess, seeing that practically all of them develop bronchiectasis, and cerebral abscess is one of the recognised complications of this dangerous disease.

Methods of Treatment.

Let us now consider the old-fashioned methods of dealing with these cases which may still be employed if modern instruments are not at hand. First, it must be noted that it is unsafe to invert and shake the patient before doing tracheotomy. Brunel's device of a couch on which he was to be inverted in order to favour the escape of a half sovereign which he had inspired is a classic in medical literature, but it is not an example to be followed, for the coin might have become impacted and so closed the career of the distinguished engineer, but he succeeded in getting rid of it *per vias naturales*, as many others have done with objects of still larger dimensions. Tracheotomy should, therefore, be performed if inversion is going to be practised, and then the patient may be turned upside down, his knees may be bent and passed over the shoulders of one or two people, and an effectual shaking carried out.

If this does not answer, or before doing it, instruments of various kinds may be introduced through the tracheotomy wound into either bronchus. Perhaps the best are such a pair of forceps as I show you which are small, bent to a suitable curve, and so arranged that when the points are opened to a slight extent the shanks are at first diminished in size. They are made on a plan first, I believe, devised by Lord Lister for removing stones from the prostatic urethra, and it may interest you to see the actual pair which he first had made for this purpose.

Another very simple apparatus may be made by bending a piece of stoutish silver wire into the shape shown. This forms an available hook which can be easily directed at will and which cannot do any damage. It will be found useful in the case of objects like tracheotomy tubes, beads, peas, &c. Then Durham's laryngeal forceps is a handy instrument, and indeed it is something of this sort which is usually employed with a bronchoscope. The tracheotomy should, of course, be a low one.

But while this method is one which may be employed by any surgeon and demands no special skill, it has the disadvantage of involving a tracheotomy with its accompanying disagreeables and risks. The introduction of the bronchoscope, which has created a revolution in the treatment of diseases in the air-passages, seems likely to transfer the treatment of these cases, at all events at first, from the general surgeon to the laryngologist.

Bronchoscopy.

This is not the place to enter into a description of the instrument.[2] It is 29 years since Mikulicz first wrote about

[1] Fortschritte auf dem Gebiete der Röntgen-Strahlen, 1909–10, p. 155.

[2] It will be found most fully described in W. Brüning's "Die direkte Laryngoskopie, Bronkoskopie, und Oesophagoskopie."

direct gastroscopy and œsophagoscopy, and before his time Kussmaul had introduced straight tubes into the œsophagus and trachea. Gottstein and others had also worked at the subject, but it is clear that to Killian and Brüning is due the credit of having evolved a practical instrument, by means of which a straight tube can be introduced not only into the trachea and the main bronchi, but even further if small enough tubes be used, as it is provided with a cunningly devised arrangement of mirrors to throw the light to the end of the tube, whilst leaving room for the introduction of swabs, probes, forceps, and other instruments.

Cocaine, with which all are now so familiar that it is difficult to realise that to many of us it seems a modern invention, is called in aid to diminish bleeding and do away with coughing; and now, if there be not much secretion, it is possible to see and, if it be removable, to remove with apparent ease, foreign bodies which are situated not further down than the end of the main bronchi. Not only so, but there are many cases on record where still smaller tubes have been passed into some of the smaller bronchi, and the foreign bodies extracted from them. As long as the idea prevailed that the root of the lung was fixed and the trachea and bronchi were more or less rigid tubes, the thought of such a proceeding would have appeared preposterous, but the facts I have already brought forward make it easy to understand that these tubes are not only subject to perpetual natural movements, but also that they can be readily shifted about at the will of the operator.

The employment of this apparatus can best be illustrated by recording the last two cases of foreign bodies impacted in the bronchi that have come within my notice.

CASE 1.—The first was that of a young woman who had been sporting with her fellows while holding a pin two and a half inches long with a glass head in her mouth. Whilst laughing the pin passed into her windpipe, and entered the left bronchus. The symptoms at the time were not severe, and she soon ceased to trouble about it, but a certain amount of cough remained, and after a time she applied to her medical man to examine her, who, finding only a few crackles along the left side of the sternum, sent her to the hospital with the observation that there was a story of a pin having been swallowed, but that he supposed it was the usual thing—incipient phthisis. A radiogram showed the pin lying rather obliquely, but not far removed from the horizontal position just above the heart shadow. On examining it, it will be seen that the image is blurred, the blurring depending mostly, but not altogether, upon the movements of the heart, to which reference has been made. Sir Thomas Barlow, under whose care the patient had been admitted to University College Hospital, asked me to see the patient, and I was obliged to suggest calling in the help of Mr. H. Tilley, who has reported the case,[3] though I could very likely have removed the pin through a tracheotomy wound. She was anæsthetised in the recumbent position with the shoulders raised and the head thrown well back. He passed the tube with apparent ease through the larynx and down the trachea, and then, watching all the while the progress of the lower end, he directed it into the left bronchus. The pin was at once apparent. He then passed down the long forceps and seized the pin. The difficulty of the operation now began, for the point of the pin had become so firmly fixed in the bronchial wall that it seemed as if it would be impossible to draw it out, and the question was whether it was safe to continue pulling, and if this was done, whether the grip of the forceps would hold. It was decided that he should make the attempt, and after a trial or two the pin broke across, and one half of it was removed. By this time a certain amount of bleeding had occurred and there was a good deal of spasmodic contraction of the bronchi. It was on this occasion that I saw that strange sight of the closure of one of the secondary bronchi. But it was no longer possible to see the remaining half of the pin, and we were reluctantly compelled to allow the patient to be sent back to the ward. She was, of course, for the next few hours in a somewhat perilous position, and I am not sure that the right practice would not have been to perform tracheotomy at once, though that would have marred the artistic success of the particular form of treatment. However, all went well; she vomited after the operation, and during one of the attacks the other half of the pin was safely expelled and the patient made a good recovery, but one cannot help feeling that there was a certain amount of what may be called luck in the *dénouement*, for the pin might have stuck in the larynx and suffocated her. She was, however, in the hospital, and tracheotomy could have been performed at any moment. I do not think one would be justified in leaving a private patient without some competent surgeon on the spot; it would have involved too much risk, but after a tracheotomy there is practically little or no danger.

While indicating the advantages of this method of treatment this case also shows one of the difficulties and dangers. For a further illustration of them the reader is recommended to consult the very elaborate article by Gottstein,[4] where he will learn how knowledge and experience increased at the clinique at Breslau, leading to the overcoming of the many preliminary difficulties. In many of their cases the performance had to be carried out through a tracheotomy wound (untere Bronkoskopie), but I imagine that the necessity for this will become less and less now that the technique has been so much improved and others are able to benefit by the experience of the pioneers.

CASE 2.—The second case was an unmitigated success. It was that of a young lady who, whilst eating some mutton broth, swallowed a piece of bone the wrong way. She was foolish enough to ask the advice of a chemist, and he had the hardihood to try to push it down with the handle of a tooth-brush. A spasmodic cough quickly set in, and lasted for two hours. The medical man who was called in could naturally see nothing; she went on coughing more or less continuously for four days, and after ten days came to London with a temperature of 100° F. A very indefinite result was obtained by an X ray photograph, and when I saw her four days afterwards, the temperature was 101° in the morning and 102·5° in the evening. There were a little deficiency of movement in the right lower lobe and a slight deficiency of the entry of air into this part of the lung. A very few crepitations were also to be heard. The cough for the moment was in abeyance, but I was told that several attacks had occurred in the course of the day. The physical signs were so slight that if one had not been aware that such is often the case in the early stages of this condition, one might have been excused for counselling delay; but I strongly urged that Mr. Tilley should be asked to see the patient next morning, and in this case the piece of bone was readily demonstrated to us at the lower end of the right bronchus, and was removed in the course of a few minutes with forceps. Already after ten days' residence in the bronchus it was soaked with pus and horribly offensive. This patient has made a complete recovery.

EXPLORATORY OPERATIONS.

Supposing it be impossible to remove the foreign body by any of the methods I have described, and that it be thought that it has made its way by a process of ulceration into the actual lung tissue, attempts may be made to discover it and remove it by means of an incision into the pleural cavity. I have only once made this attempt, and that was not successful. It was in the case of the boy with the peg-top before referred to. I made only a small opening into the pleura, introduced one finger, and felt as completely as I could over the back of the lung. But it was before the days of the X rays, and we did not even know where the piece of iron was or even for certain that it was there at all. Even without the employment of the Oberdruck und Unterdruck methods which have recently been introduced from Breslau, it would be justifiable, I think, to make a larger opening in the pleura in order to conduct such an exploration, because it is well known that if the superficial tissues be accurately closed the pneumothorax which has been caused will be rapidly absorbed.

I would remind you of what is meant by the Oberdruck und Unterdruck methods with which the names of Brauer and Sauerbruch are respectively associated. In the former case the head of the patient is inclosed in a hermetically sealed chamber which may or may not contain also the hands of the anæsthetist. In either case the anæsthetic is supplied at a pressure slightly above that of the normal atmosphere. In Sauerbruch's apparatus, the body of the patient and the operator are inclosed in a large chamber in which the

[3] Transactions of the Royal Society of Medicine.

[4] Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie, Dritter Supplementband, Jena, 1907, pp. 279, 415.

pressure is below that of the atmosphere, whilst the patient's head and the anæsthetist are outside. It is easy to see that by either of these methods it will be possible to regulate the extent to which the lung recedes from the chest wall when the pleura is opened, and also, when required, to inflate it again so as to bring it in contact with the chest wall. But for our particular purpose it has this defect, that if one of the large bronchi is opened the physical conditions are obviously altered and the control over the lung could no longer be maintained. This objection does not, however, apply to cases where the foreign body is in the substance of the lung and where it may be possible after its extraction to hermetically close the incision in the lung by which it has been removed. But another objection at once suggests itself—namely, that the portion of the lung incised is sure to be septic, and therefore it must be a dangerous thing to complete the operation by sucking out the lung and then closing up the chest wall. Or, if not dangerous, it is at all events very likely to be followed by a septic empyema. The safest plan would be, if it were possible, to draw out the lung to the opening in the chest wall and secure it there by stitches, while at the same time accurately closing the pleura; in fact, treating it like a pulmonary abscess. It does not seem likely that these two methods would be largely employed in dealing with this class of cases. At present the apparatus is very costly, and of the cheaper forms which have more recently been devised, it does not appear that any as yet have been placed upon the market.[5]

A Presidential Address

ON

THE PRECIPITIN TEST IN MEDICO-LEGAL WORK.

Delivered before the Section of State Medicine, Royal Academy of Medicine in Ireland, on Jan. 28th, 1910,

BY E. J. McWEENEY, M.A., M.D. R.U.I., D.P.H., F.R.C.P. IREL.,

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, UNIVERSITY COLLEGE, DUBLIN.

1. NATURE OF PROBLEM.

GENTLEMEN,—In medico-legal work it is often of great importance to ascertain the source of a blood-stain—the species of animal that furnished the blood of which the stain is composed.

Until the method of which I now desire to speak came into use, the difficulties in the solution of the problem as to the origin of a given blood-stain may be described as practically insuperable. It must be borne in mind that in medico-legal work, where the life of a fellow-man hangs in the balance, nothing short of absolute certainty ought to suffice, and the only method hitherto available—the microscopic appearance of the blood corpuscles—falls far short of yielding the absolute certainty required. The stain when submitted for examination is practically always dry and has been so for days or weeks, not infrequently for months or years. The erythrocytes have become fused together, their outlines indistinct and distorted, their substance closely adherent to, or entangled in, the stained material.

In this country the mammals the blood of which has most usually to be distinguished from that of man—viz., the ox, horse, sheep, pig, goat, and rabbit—possess red corpuscles differing so slightly from those of man that only a skilled microscopist, well versed in micrometric work, could hope to distinguish them with certainty from those of man in the perfectly fresh condition. There is no difference in shape, and the size varies within the narrow limits of a few microns. The red corpuscles of man average 7·7 μ, those of the horse 5·6, of the ox 5·6, of the sheep 4·5 to 5·0, of the goat 4·25, of the pig 4·6 to 6·0, and of the rabbit 7·0 to 7·5. In the fresh preparation such differences are, of course, quite appreciable, and may be relied upon when a sufficient number of unaltered corpuscles of each kind are available, so that a well-grounded average value may be determined. But how different is the case in medico-legal work!

Speaking from personal experience of many cases which I have examined, I can say that it is extremely difficult to obtain from stains dried on fabrics or solid surfaces isolated corpuscles in a condition satisfactory for micrometry. Much depends on the fluid used for isolating the corpuscular elements. A large number of formulas have been suggested, of which the best that I have tried is a 32 per cent. solution of caustic soda or potash. But even careful maceration in this fluid yields too many forms, deformed in shape and differing so widely in size, that even with stains of known origin it is difficult to convince oneself that any reliable distinction can be drawn by the aid of the microscope—and this, too, in stains that have only been quite a short time dried—a few hours in the incubator.

It is a commonplace of the books that the circular non-nucleated erythrocytes of the domestic mammals can be readily distinguished from the larger, elliptical, nucleated erythrocytes of birds, reptiles, and fishes, and a mere glance suffices to tell the difference *in the fresh preparation*. But when we come to the conditions that prevail in actual practice, the distinction is far from being such an easy matter as would at first sight appear. Shape and size may be veiled by distortion; nuclei when present may disappear or become hard to recognise; when absent, may be simulated by highly refractive granules or dark central areas. Attempts to wash out the stains with water may have produced hæmolysis. From many blood-stains I have failed to isolate any red discs that could be relied upon to supply an answer to the question, Was this blood mammalian?—much to the surprise of jurists who had been led by the statements in the books to suppose that so much at least could be certainly ascertained and deposed to on oath.

We have advanced a long way since 1900, when the diagnosis of mammalian blood was the highest limit of certainty attainable by the medical jurist. Two cases that have lately occurred in my own experience may serve as examples of what can now be accomplished, thanks to the method of sero-diagnosis which I am about to describe. The clothes of a man who was accused of committing a murder having been submitted to me for examination, I found on one article only, the cap, a stain of blood. It was about the size of a threepenny-piece, and appeared to be a single drop which had fallen on the cap from above, and dried on the cloth undisturbed. The stain had evidently been there a considerable time, for on microscopic examination of scrapings macerated in 32 per cent. soda the red corpuscles appeared so shrivelled and distorted that I could come to no conclusion as to their origin, merely noting that they were of mammalian character and seemed a little small for those of human blood. It did not, however, occur to me at the time that they were of other than human origin. On applying the precipitin test, I found that they gave the reaction characteristic not of human but of horse blood. This result I duly reported, giving it as my opinion that the blood was of equine origin. On subsequent inquiry it turned out that the accused man was in the employment of a large horse-dealer, and was frequently engaged in assisting at operations performed on horses, more especially in the region of the mouth; so that a drop of horse blood might readily have fallen unobserved on to his cap and dried there.

The second case was that of a man accused of a particularly brutal murder. On his "leggings" and trousers I detected a number of blood-stains, also on a knife which was found concealed in moist earth and was conclusively traced to the prisoner. A witness who remarked the appearance of the prisoner's knife, when he took it out to cut some twigs for a broom, was told by him that he had been killing a goat. From each of the articles mentioned I succeeded in obtaining a sufficiency of extract for the application of the test, and at once obtained the typical precipitation reaction with human antiserum, and a negative result with the other antisera against which I tested it. The human origin of the stain was thus proved. The murderer, whilst awaiting trial, confessed his crime, and has since suffered the extreme penalty of the law.

2. GENERAL NATURE OF PRECIPITIN TEST.

I will now briefly state how this valuable test originated. Its history will explain how it was that I came to take it up. Precipitins belong to the class of specific antisubstances or

[5] A short description of these will be found in the last volume of Burghard's System of Operative Surgery, vol. iii., pp. 703-708.

immune bodies. They were discovered by bacteriologists during the investigation of the properties of the blood serum upon which depends immunity against infective disease. It was whilst following in my own laboratory the results that had been achieved in Germany by Uhlenhuth,[1] Wassermann and Schütze,[2] and by Nuttall[3] in Cambridge that I was enabled to convince myself of the objective reality of the phenomena in question and of their ready applicability in practice. Having tried the precipitin method in various ways and with every conceivable control, and having mastered the technique (which requires a good deal of time and perseverance), I brought the matter under the notice of the Irish Government in 1902 and have been entrusted by them with the conduct of such investigations in criminal cases.

During the seven years that have since elapsed I have been many times subjected to cross-examination with reference to the exact nature and reliability of the test. Save on one occasion I have always succeeded in explaining it to the satisfaction of the court. But, incidentally, I have found that even in our own profession there exists a great deal of misconception with regard to this matter. Passages from standard text-books on medical jurisprudence have been again and again quoted against me, and my attention has been called to the absence of any official recognition of the test on the part of the English Home Office. For these reasons I have thought it well to avail myself of the opportunity afforded by this presidential address to state in the clearest and least technical language I can command the nature of the test, the technique of its application, and the precautions that have to be taken in order to guard against error. I am writing, not for experts on immunity, but for those members of my own and the legal professions who, being without special knowledge of the subject, are desirous of knowing what has been, and what can be, accomplished by the aid of these new tests and how they are to be carried out.

As I have said above, precipitins belong to the class of substances called antibodies which arise in the blood and tissue liquids of animals (including man) as the result of the entrance of certain foreign substances into the animal economy. Not every foreign substance is capable of giving rise to an antibody. In order to do so the introduced substance must possess a certain molecular complexity—must, in fact, be similar in its general nature to the substances which the cell is in the habit of taking in as food, and for the admission of which it possesses what Ehrlich calls receptors. Extraneous substances of simple molecular constitution, which are unlike food and for which the cell does not possess any receptors, are incapable of giving rise to the formation of antibodies. Simple metallic substances, such as arsenic, alkaloidal substances like strychnine, and carbohydrates such as sugar and starch, are therefore incapable of giving rise to immunising antibodies, though a certain amount of immunity against poisons like arsenic or morpineh can be produced by gradually acclimatising the system to their presence—a totally different matter.

In general terms it may be stated that the introduction into the system of a foreign substance of albuminous or proteid nature leads to the formation of an antibody which is found in the serum of the animal so treated. A substance capable of so acting is called an *antigen*. When antigen is brought into relation with serum containing antibody, a reaction takes place between the two, roughly comparable to that which takes place when an acid is brought in contact with an alkali. The two may be said to combine and neutralise each other. The effect may be at once perceptible to our unaided senses, or it may require to be demonstrated by special methods. The following are amongst the chief kinds of antibodies: (1) antitoxins, (2) precipitins, (3) agglutinins, (4) opsonins (in part), and (5) lysins.

Poisons of complex constitution and derived either from animals (snake and spider poison), from the higher vegetables (abrin, ricin), or from bacteria (diphtheria, tetanus), are the genetic bodies of antitoxins. When a toxin is brought into contact with its antitoxin no visible change is produced, but the combination is non-virulent, owing to the occupation of the haptophore group of the toxin, on Ehrlich's hypothesis.

Agglutinins and opsonins come under the head of antibacterial substances, and so do bacteriolysins. The antigen is the micro-organism, and the effect of bringing antigen and antibody into contact is the agglutination, or phagocytosis (in the presence of leucocytes), or solution of the genetic organism, as the case may be.

Under the head of lysins come not only the bacteriolysins just referred to, but also cytolysins, the genetic bodies being cells foreign to the animal into the economy of which they are introduced. The most important of these are the hæmolysins, which are evoked by the injection of foreign red-blood cells. The effect of bringing the antibody (hæmolytic serum) into contact with the antigen (blood corpuscles of the kind used for injection) is that the cell stroma is ruptured and the hæmoglobin diffuses through the liquid. This "laking" of the blood, as it is called, is the most easily observed of all phenomena of this class and is extensively used for the detection of antigens and antibodies by the method first suggested by Bordet and Gengou[4], more fully worked out by Wassermann[5] and his colleagues, and now generally known as complement-fixation.

For the present, however, we shall confine ourselves to the antibodies that more immediately concern us—viz., precipitins. The antigen of these is serum-albumin or globulin. Any albuminous tissue fluid, even urine (as was, I believe, first shown by Ruffer), can, when injected into an animal of another species, act as antigen. The effect of the addition of serum containing antibody to liquid containing antigen in solution is the production in the previously clear liquid of a haze or opacity which gradually thickens and condenses into little white flocculi. These gradually sink to the bottom and form a cloudy deposit technically called the *precipitum*.

Like all these substances, the precipitating antigen is *specific* in its action. This means that it will produce the above effect *only with its own antigen*, not with antigen derived from any other species of animal, save that which furnished the albumin employed for the injection. This specificity is the keynote of all these reactions and explains their utility in practice. It is not, however, absolute. An antibody produced by injecting albumin from one species will react with antigen from a closely-allied species, as was pointed out by Nuttall[3] in his admirable researches on blood relationship. For example, precipitins made by injecting human antigen will react with the albumin of the higher apes, sheep antibody will react with goat antigen, rabbit antibody will react with hare antigen, &c. But the reaction is, in comparative experiments with properly diluted material, found less distinct with the allied than with the identical antigen, and in this country, where identification of human blood is chiefly required, this source of error is not of much importance and can readily be eliminated by proper controls, as will be explained later on.

Of greater importance is the so-called "mammalian reaction" yielded by certain highly potent antisera, by virtue of which their reactions extend to antigens derived from animals rather widely removed biologically from those which furnished the albumin used in the injections. Errors from this source can readily be avoided by employing the antigen in highly dilute solutions (1 in 500–1000).

3. TECHNIQUE.

The first and most difficult part of the procedure is to obtain the antibody. For this purpose I have always used rabbits. As antigen I have sometimes used human blood obtained, with due precaution against contamination, from the placenta during and after parturition. This is troublesome to obtain and must be used fresh, as it is seldom uncontaminated and micro-organisms speedily make their appearance in it even when stored in the refrigerator. Where antigen blood or serum is difficult to obtain, or can only be had at long intervals, it would be quite possible to dry it over sulphuric acid in a vacuum or in the incubator soaked into filter-paper. Once dry it can be sterilised at 150° without loss of its antigenic property, and can then be stored indefinitely and when needed brought into solution with normal saline solution, or if preferred with sterile distilled water to which an equal volume of 1·7 per cent. saline solution is added. What I now invariably employ is ascitic or pleural effusion, or hydrocele fluid obtained as aseptically as possible and stored over chloroform. The chloroform can be got rid of by pipetting some of the clear supernatant serum into a sterile Petri dish and leaving it overnight in the incubator, covered only with sterile filter paper. Blood of domestic animals can, of course, be readily obtained from the slaughter-house.

Some of the serum (3, 4, 5, or 10 c.c.) is injected into

a rabbit, either intraperitoneally or into the marginal vein of the ear, with all due precautions, and the injection repeated at intervals of four or five days until 25 c.c. have been introduced, when the animal may be bled from the ear and the serum tested as to its content in antibody. The process of bleeding is much facilitated by wrapping the ear in a piece of lint wrung out of hot water. The veins become dilated and the yield of blood is greatly increased. The blood from the divided vein is taken up into a Wright's pipette or allowed to rise into a small test-tube with an obliquely drawn out capillary end. Should there be evidence of the presence of antibody, such as the production of a distinct opalescent zone at the line of contact with the antigen serum diluted 1 in 100, then the injections are proceeded with till the rabbit has received 70 to 80 c.c. of antigen. Much smaller quantities are often effective. 10 to 14 days after the last injection the animal is chloroformed and bled either by dividing the vessels of the neck or by quickly opening the thorax, cutting the great vessels and rapidly pipetting off the blood with which the thorax is filled into a sterile Petri dish, which is propped up obliquely in the refrigerator till the serum has separated. The serum is then drawn up into sterile pipettes and sealed off and stored in the refrigerator. In practice it is difficult to avoid contamination by hairs, &c., and the serum will seldom keep at room temperature unless filtered through a small Berkefeld candle or treated with 1/10 of its volume of 5 per cent. phenol. I have found, however (in agreement with Graham Smith and Sanger[6]), that even specimens of antiserum that smelt badly on opening the tube, and the deposit from which contained anaerobic spores, gave quite useful precipitating reactions if care were taken not to stir up the sediment. Uhlenhuth[7] found that mould-growths did not interfere with the specific power of the serum. The turbidity due to such growths must be allowed to subside or be got rid of by centrifuging. A plan that seems well worth trying is that recommended by von Eisler,[8] of drying the antiserum on strips of black paper—the so-called *Naturpapier*. If only small quantities of antiserum are needed at a time, the animal yielding it can be kept alive for many months and its serum be maintained at a very fair level of potency by an occasional injection of antigen. As cachexia is, however, apt to supervene, and the *titre* has to be re-determined each time, this course is not to be recommended.

The process is tedious and liable to cause disappointment. Some batches of antigen prove toxic. I have had a specimen of pig-serum, freshly collected and to all appearance normal, which killed rabbits in doses as low as 2 c.c. intravenously injected. In other cases cachexia supervenes, more especially if the injections are massive (10 c.c. and more). It is important to make a practice of weighing rabbits at frequent intervals, as if they waste, their serum is useless. Another frequent source of loss is anaphylaxis,[9] which usually occurs at the second injection, especially if it has been a large one. Highly immunised rabbits, the preparation of which has cost much time and trouble, sometimes die from unknown causes in the night, and their serum is thus lost. In order to avoid disappointmemt, if it is absolutely necessary to have some highly potent precipitating antiserum in readiness by a certain date, it is well to start preparing three rabbits at least eight or ten weeks beforehand.

Before applying it for medico-legal purposes, it is absolutely essential to ascertain the potency of the antiserum. For this purpose small test-tubes are used, about 5 cm. long by 5 mm. in bore. They are conveniently made fresh each time from glass tubing, and are placed in little racks with holes for half a dozen. These racks I have had specially made by a tinplate worker. With an ordinary drawn-out capillary pipette I place in the bottom of each about 0·05 c.c. (3 drops) of the serum to be tested, and superpose on its surface with another pipette about 0·1 c.c. of antigen serum diluted with normal saline solution 10, 50, 100, 500, and 1000 times. By way of control a second set of tubes is charged with the antiserum and treated in the same way with the serum of some other animal similarly diluted. Both antiserum and antigen should be absolutely clear, and the line of demarcation between them sharply marked. Personally, I have not been much troubled by opalescent antisera, but if encountered they should be rejected.

Observation is made from time to time up to an hour, the tubes being left meanwhile at the ordinary temperature of the laboratory. The presence of a distinct line or zone of opalescence at the junction of the fluids indicates a positive result. The appearance is not unlike that produced by the nitric-acid test as usually applied to albuminous urine. With a powerful antiserum and a strong solution (1 : 100) of homologous antigen the opalescence gradually spreads through most of the supernatant fluid and resolves itself into flocculi which by the following day will be found to have sunk to the bottom of the tube. When the antiserum is weak or the antigen very dilute (1 : 10,000–20,000) the zone may require careful scrutiny by a trained eye and suitable oblique illumination against a dark background for its detection.

I have found that antisera giving a distinct zone within an hour with antigen diluted 1000-fold are quite strong enough for all practical purposes, though I am aware that stronger ones are considered necessary by the German workers. So completely can the test be controlled in actual practice that even comparatively weak sera, reacting only with a 100-fold dilution of antigen, can be made to yield conclusive results.

Highly potent antiserum when brought in contact with strong solutions of antigen may (and very often does) give rise to pseudo-reactions—i.e., precipitates with non-homologous serum or stain extract. Errors so arising are to be avoided by using the antigen diluted to somewhere about the limit of the titre of the antiserum—not stronger at any rate than 1 per 1000, and by careful controls with as many other sorts of antigen as are available, in similar dilutions.

Nuttall[10] has suggested and worked out a method of measuring the amount of precipitin formed in unit time, and comparing it in tubes containing the same antiserum with different antigens. This method does not seem to have been widely practised, and it appears to me that differences in the density of the precipitum might readily affect its apparent bulk, unless, indeed, it were concentrated by the centrifuge. Personally, I have not tried the method, and prefer to base my opinion upon the rapidity and distinctness with which the reaction comes on in the zone of contact between highly potent antiserum and highly diluted antigen.

4. TESTING THE STAIN.

Having obtained a satisfactory antiserum, the next step is to prepare an absolutely clear solution of the stain to be tested. Before proceeding to do this, however, it is necessary to prove that the stain consists of *blood*. This must be done by the usual methods. I always use the benzidine test[11] first, and, should this prove positive, confirm it by the demonstration of hæmin crystals and the spectroscopic reactions of the pigment, using a small Browning spectroscope or the Abbé micro-spectroscope, if the amount is small. I always put up a preparation in 32 per cent. soda so as to observe the character of the corpuscles.

One must not lose sight of the fact that the precipitin reaction reveals the presence, not merely of blood, but of any albuminous substance, such as mucus, pus, semen, milk, or albuminous urine derived from the animal that has provided the antigen used for preparing the antiserum. The necessity for proving that the stain-producing substance is blood therefore remains.

This having been satisfactorily demonstrated, the next thing to do is to prepare a solution of the stain in normal saline solution, and to render it absolutely clear and bright by filtration and the centrifuge. If the amount of material is large, considerable care must be taken not to use it too strong, lest pseudo-reactions give rise to error. It should be colourless, or nearly so, foam on shaking, and give a slight but distinct reaction with the nitric-acid test for albumin. Should the amount of solution available be very small—less than 0·05 c.c., the reaction must be carried out in small pear-shaped or lengthily oval pieces of capillary tubing, the liquids being introduced by means of finely drawn-out capillary pipettes.

It is absolutely essential to carry out side by side with the actual test, a complete series of controls. For this purpose we need blood-stains of man and the chief domestic animals on various substrata. Sheets of filter-paper are the most convenient of these, but it is well to have the blood dried on woollen, linen, and cotton fabrics, also on leather, wood, and metal. This dried material should be of various dates so that one may select for control a specimen not more recent than that under investigation. In addition to the stains of known origin, one ought also to possess at least one

other antiserum made with an antigen different from the one under investigation. Thus, if human blood be suspected it is well to have in hand some rabbit serum anti to, say, ox-albumin. For obvious reasons the larger one's stock of these antisera the better, and I now endeavour to keep in stock those reacting with the albumin of the horse, ox, sheep, and pig. Lastly, one needs some serum from a normal non-immunised rabbit.

Two of the little stands are now taken, each containing six small test-tubes. Each of the tubes in the first stand now receives 0·05 c.c. anti-human serum. With capillary pipettes about double the amount of one of the following dilute solutions is now added to each respectively:—

Test tube	1	receives	extract	of	known	human	stain.
,, ,,	2	,,	,,		,,	ox	,,
,, ,,	3	,,	,,		,,	horse	,,
,, ,,	4	,,	,,		,,	sheep	,,
,, ,,	5	,,	,,		,,	pig	,,
,, ,,	6	,,	,,		stain under investigation.		

The second stand of tubes is now charged as follows:—

Test-tube	1	receives	normal	rabbit	serum	about	0·05 c.c.
,,	2	,,	anti-human	,,	,,	,,	,,
,,	3	,,	,, ox	,,	,,	,,	,,
,,	4	,,	,, horse	,,	,,	,,	,,
,,	5	,,	,, sheep	,,	,,	,,	,,
,,	6	,,	,, pig	,,	,,	,,	,,

About 0·1 c.c. of the extract of suspected stain is now carefully superposed on each with a capillary pipette as above described.

The tubes are observed in 15 minutes and again at the end of an hour. Should the stain be of human origin only Nos. 1 and 6 of the first stand and No. 2 of the second stand should show a positive reaction. The negative results in the remaining tubes of the first stand prove that the antiserum used is specific—i.e., will only react with its own antigen. The negative results in the second stand show that the stain is composed of specific human antigen reacting only with its own antibody.

Should the stain be of non-human origin it will, of course, react in the tube (if there is one) containing the corresponding antibody in the second series, and the conclusion as to its nature can be confirmed by a proper series of controls.

Let us return now to the two concrete cases mentioned earlier in this paper. In the case of the blood stain on the cap, the amount of extract available for the test did not exceed 0·1 c.c. By the capillary-tube method, however, I was able to superpose enough of it on the surface of five different antisera to assure myself that it reacted powerfully with the anti-horse serum, whilst it proved negative over anti-human, anti-ox, anti-sheep, and anti-pig serum respectively. In another series of tubes I tested the specificity of the anti-horse serum used, by running on to its surface a little highly dilute stain extract from horse, man, ox, sheep, and pig respectively, and obtained a reaction in the first tube only. The demonstration of the specific nature of the reaction was thus completed and the origin of the stain determined beyond all possible doubt.

In the other case above referred to, the extract from the several articles submitted, at once reacted with anti-human serum, but not with sera anti to the albumin of the ox, sheep, pig, or horse. I had no anti-goat serum on which to try it, but the anti-human serum I was using gave no reaction with extract of goat-stain, so that the positive result with anti-human serum was conclusive.

5. SENSITIVENESS OF THE TEST.

Coming now to the delicacy of the method, my opinion, based on experience of many cases, is that if the operator has at his disposal a powerful antiserum and good command of capillary-tube technique, the amount of albumin demonstrable by this test is amazingly small. The chief difficulty in my experience is not the smallness of the amount of antigen, but the difficulty of obtaining a satisfactorily clear solution. Filtration of such minute quantities of stain extract is, of course, out of the question, and we must only have recourse to prolonged centrifugation at high velocities, which is usually successful.

I have never attempted to ascertain the smallest amount of antigen demonstrable by this means, but Uhlenhuth[12] says that it is easy to demonstrate 1-20,000th gramme and that Hauser was actually able to demonstrate as little as 1-200,000th part of a gramme by the use of the capillary-tube method due to Carnwath.[13]

My original intention was to refer in this address to the other sero-diagnostic method of albumin differentiation, that introduced with another object by Bordet and Gengou[4] and now well known under the name of complement-fixation. This reaction depends on the property possessed by mixtures containing antigen and the corresponding antibody, of fixing complement, and thus preventing the hæmolysis of sensitised corpuscles. It can be used for the detection of amboceptors (antibodies) in the presence of the corresponding antigen or for the detection of antigen in the presence of the corresponding amboceptor (antibody). It has been used successfully for the detection of infection by known and cultivable micro-organisms (typhoid, cholera, tubercle) and also when the infecting organism is unknown or uncultivable. Its principal application has hitherto been in the latter class of case, when it often affords the only available method of making the diagnosis. The infection to the recognition of which it has been mainly applied is that of syphilis. Wassermann first succeeded[14] by its means in demonstrating syphilis amboceptors in the humours of tabetics and paralytic dements.

It is to Neisser and Sachs[15] that we owe the introduction of complement-fixation into medico-legal practice. Their work was based upon the results of Moreschi[16] who first showed that complement is fixed by the union of precipitin with its homologous precipitinogen (antigen). Inasmuch as precipitins are generally looked upon as receptors of the second order provided with a precipitating and a haptophore group, and ordinarily act independently of complement, it is not exactly clear at first sight how the fixation takes place. It is certain that amboceptors are produced during immunisation with foreign albumin, and that during the process of precipitation they unite with their corresponding antigen and throw down or fix complement. Those who desire precise information as to what goes on during the interaction of these specifically opposed substances are referred to Professor R. Muir's brilliant series of researches published in the *Journal of Hygiene*, and now collected under the title of "Studies in Immunity. Be the explanation what it may, the fact remains that complement is fixed by the union of almost inconceivably minute traces of albumin with its corresponding antibody. The quantity of the combining substances is far too small for any precipitate to be visible, yet the fact that the union has taken place may be proved by the absorption of the complement necessary for the re-activation of an inactive hæmolytic system.

I have some little experience of the test, and hope as time and opportunity offer to accumulate some more and lay it before the Academy on a future occasion. Meanwhile, I will only say that complement-fixation is a very troublesome and time-consuming procedure when carried out with all the proper controls, and without them it has no scientific value. It is much more difficult than the precipitin reaction, and can hardly be carried out satisfactorily in a laboratory where any other work is going on. Moreover, it is excessively delicate, so much so that, as pointed out by Uhlenhuth, even the trace of protein contained in sweat may fix some of the complement. There are other sources of error. Thus, for example, there are present in various fabrics used for clothing, complement-fixing substances,[17] the presence of which has to be specially tested for, and this complicates the already over-elaborate technique. This drawback may be got over in some cases by showing that the substances in question are heat-stable, which is not the case with blood, and in others by the use of artificial hæmolytic amboceptor, instead of naturally hæmolytic serum as originally recommended. I am inclined to agree with Uhlenhuth when he says (*loc. cit.*) that the delicacy of the precipitin test (which can detect 1-20,000th gramme of foreign albumin) suffices for all practical purposes, and that it must seldom be necessary to invoke the aid of complement-fixation in medico-legal work.

Outside of medico-legal work there have been found several interesting and valuable applications for the precipitin method, which I will, in conclusion, briefly touch upon. There is, for example:—

(*a*) The diagnosis of bacterial infections by adding the serum of the infected animal (antibody) to the culture fluid of the suspected organism, filtered free from the bacteria

bodies, but containing their soluble extract or metabolic products (antigen). If the two correspond a specific precipitate is produced, the formation or absence of which can be utilised for diagnostic purposes, as was first, I believe, shown by Wladimiroff in the case of glanders infection of the horse. The reaction has been found to work well in the case of typhoid, cholera, and streptococci. This procedure has been very fully studied by R. Kraus, to whom we owe most of our knowledge on the subject.[18]

(*b*) The recognition of the species of animal from which almost any given tissue or albuminous fluid has been obtained, not merely blood or serum. Thus, for example, by injecting cow-milk serum into rabbits, Fish[19] was enabled to obtain an antiserum (lacto-serum) which produced a specific precipitate with the serum of cow-milk, but not with that from other animals, and which could therefore be employed for diagnostic purposes. It would seem that even boiled milk can have its origin so determined. Working on these lines, Sion and Laptes[20] claim to have traced the origin of samples of cheese. Similarly, in the case of egg-albumin, Myers and Uhlenhuth[21] found that specifically different antisera are yielded by rabbits injected with the whites of the eggs of different species of birds. In this way it was found possible to determine whether a given sample of egg-white was produced by a common fowl, a duck, a turkey, or a plover.

A further application of this reaction which has proved of the utmost practical value in meat-inspection is that whereby the nature of a given sample of muscular tissue can be determined. Rabbits injected, not necessarily with muscle-juice, but with the blood or serum of, say, the horse, dog, or cat, yield antisera which, when brought in contact with extracts of the muscle-tissue of these animals, give rise to highly specific precipitates. In this way it is possible to ascertain the species of animal from which a given piece of flesh was cut, and to refer the several components of a sausage to their respective origins. The German Public Health Administration has taken advantage of this discovery, and now actually prescribes the use of the precipitin reaction in cases of suspected importation of forbidden kinds of meat, adulteration of sausages with horse or dog flesh, &c.

Along these lines it would be possible to determine the origin of the various kinds of meat extract that are now on the market, provided that they had not been heated to such a point as to destroy their specific antigens. This has actually been accomplished in a few cases, and the claim that the extract was made from beef was substantiated in the case of one brand, whilst in another the only albumin demonstrable was found to be derived from hens' eggs![22] An interesting and valuable field of work is thus thrown open to the food analyst who is possessed of the necessary biological training and the requisite facilities for animal experiment. Nor is the applicability of the method confined to albumins of animal origin. Antisera have been made[23] whereby the protein of the grains of cereals can be differentiated from that of the legumes.

(*c*) Different *kinds* of protein derived from the *same species* of animal can sometimes be thus differentiated. Hamburger[24] was able to obtain antisera differentiating the albumin from the casein of cow's milk. Uhlenhuth,[25] by injecting separately the white and the yolk of hens' eggs into different rabbits, was able to obtain antisera specific for each. Of more direct medical interest are the experiments of Weichardt[26] and Liepmann,[27] who by injecting rabbits with placental syncytium were able (by the method of elective saturation) to obtain a serum capable of precipitating one kind of albumin only—that derived from syncytial cells. From this it would appear to be only a short step to obtain antisera exercising a specific action on cancer cells or the albumin derived from them, supposing (which is not certain) that such cells possess any specific properties not shared by the normal epithelium at their seat of origin. Experiments have been made in this direction, but so far as I am aware without success.[28] In this connexion it is interesting to note that by injecting extracts of crystalline lenses from different animals, Uhlenhuth[29] found that the antisera so obtained did not react with the serum or extracts of other organs of the animal that provided the lenses used for the injections. Antisera made from the lenses of various animals (man, pig, fowl, frog) were found to react equally well with the extract of the lens of any animal. From this it would appear that the lens contains an albumin *sui generis*, specific for the organ, but not for the species, and not sharing the biological properties of the blood-derived albumins of the rest of the body. This is a highly interesting observation when viewed in the light of what we know with regard to the origin of the lens from the embryonic ectodermal epithelium. Römer[30] has made use of it to support his theory that senile cataract is due to cytotoxic influences.

(*d*) Lastly, an interesting controversy has arisen as to whether a precipitin reaction can be obtained from the tissues of Egyptian mummies that have been preserved for thousands of years. The inquiry was led up to by the ascertained fact that the origin of bones that have been buried for various periods can be revealed by the precipitin reaction, provided that an extract containing dissolved albumin can still be obtained from them. As the result of their investigations carried out on Egyptian mummies from 3000 to 5000 years old, von Hansemann and Meyer maintain that their tissues react to anti-human serum with sufficient distinctness to enable their human origin to be so demonstrated. On the other hand, Uhlenhuth completely failed to obtain from 27 Egyptian and Peruvian mummies which he tested, any extract capable of yielding a precipitin reaction. Indeed, he states[31] that he failed even with a mummy only 300 years old. In this negative result he is confirmed by Schmidt of Cairo,[32] who was able to obtain from a mummy of the prehistoric period (at least 6000 years old) an extract containing sufficient albumin to give a biuret reaction, but failing to yield a precipitate with human antiserum. The proteid matter would seem to have undergone some radical change during its long period of preservation.

In these latter observations I feel that I have wandered far from my proper subject. But I felt sure that in an opening address such as this, a somewhat general survey of the possibilities of the precipitin method would not be unwelcome to our Section of State Medicine.*

OBSERVATIONS ON CONJUNCTIVITIS.[1]

BY ROBERT W. DOYNE, M.A. OXON., F.R.C.S. ENG.
READER IN OPHTHALMOLOGY, UNIVERSITY OF OXFORD.

ON looking through the answers to the questions I set of the various forms of conjunctivitis I was struck with the enormous number of varieties that from the text-book standard might be enumerated. I wondered whether we were not adopting a sort of ready reckoner style, and whether the simple facts of conjunctivitis might not be lost sight of in the morass of nomenclature. There would be less to complain of if the names were consistently selected, either from the appearance or from the cause, or from the character of symptoms, but no such method is adopted. Some forms are described by names that are a survival of an older nomenclature, such as blennorrhœal, catarrhal; often names are chosen from the appearance of the discharge, mucopurulent, membranous, or from different characteristics, as nyctalopic, angular, follicular; others again from the exciting cause, pneumococcal, diplobacillary, gonococcal, so that without much difficulty one can place exactly the same condition in two or more categories. Instead, therefore, of accurate differentiation, confusion is rendered worse confounded.

I pray that we may be delivered from what used to be the deadly sin of dermatologists, among whom each man was a law unto himself as regards nomenclature, and few realised what his *confrères* were talking about. Let us not forget that conjunctivitis should mean no more and no less than inflammation of the conjunctiva. If, on the one hand, more should arise it is a sequela; on the other hand, for instance, a hyperplasia of the normal lymphoid tissue of the conjunctiva constituting follicles is not conjunctivitis until the follicles become inflamed.

The conjunctiva is that structure that extends from the margin of the skin of the lids to the limbus corneæ, beyond which it is represented by the corneal epithelium, thus constituting a sac. The epithelium at the lid margins is stratified and this form extends for a short distance. It soon becomes of cylindrical type comprising two layers, the deeper rather flattened, the superficial cylindrical. As it approaches the cornea it becomes again stratified, and this form covers the cornea. Goblet cells also form apparently from the deeper layer which discharge their contents, but do not regenerate and are themselves cast off. The subepithelial structure has been divided into two, both fibrous, the more superficial containing a large amount of adenoid tissue, while in the deeper, thicker, and much more densely fibrous connective-tissue corpuscles a large number of lymphocytes are normally present. True papillæ only form near the limbus corneæ. Arteries, nerves, and lymphatics run chiefly in the deeper fibrous layer.

When this structure becomes inflamed it follows the usual course of inflammation from whatever cause arising, the difference being only of degree. The vessels dilate, the capillaries become crammed with leucocytes and red blood cells; in the veins the leucocytes collect along the vessel walls, and there is a general stasis. Then the leucocytes and the blood plasma transude; the lymphocytes normally present in the tissue enormously increase; the former wander through the tissues and show their characteristics of polymorphonuclear cells and reaching the surface are cast off as pus. Mast cells and plasma cells increase the effusion which produces the swelling known as chemosis. The goblet cells secreting mucus greatly increase as the inflammation proceeds, and these constituents go to form the "discharge." Sometimes the vessels become plugged or the fibrine-forming factors of the blood plasma that has transuded form a membrane on the surface of the conjunctiva involving the epithelial layer, or in more aggravated cases the coagulation takes place in the structure of the lid, and the tissue becomes solid like wood.

Now this is briefly what occurs in varying degrees when the conjunctiva is inflamed. As a rule, the causes are so readily disseminated that the attack is general, but from some causes it may be more or less localised, and in a few it is strictly so.

Now, the incidence of some attacks of conjunctivitis may be fairly regarded in the light of an attack on the vitality of the patient by a foreign army of infection choosing the conjunctiva as a battle-ground, while other attacks represent a mutiny on the part of those whose special function is to preserve order. The first simile refers to the action of the various pathogenic micro-organisms that have been isolated, the second to neuropathic conditions, such as herpes, pemphigus, and perhaps phlyctenules, and if in your mind you carry further the similes you will recognise how closely the fact of victory or defeat or guerrilla warfare corresponds with actual facts of the inflammation. Now, as to these micro-organisms, if you will allow me to change my metaphor to the more mundane one of a police court, some have been caught red-handed and are convicted, and these include streptococci, pneumococci, gonococci, diplobacilli, Koch-Weeks and tubercle, while grave suspicion attaches to staphylococci, and circumstantial evidence is dead against Klebs-Löffler bacilli in membranous conditions, while several others are under supervision.

The chief agent in producing what used to be called mucopurulent conjunctivitis, catarrhal conjunctivitis, and "pink eye" is the Koch-Weeks bacillus. Quickly as it loses its malignancy, difficult as it is to grow, yet it is responsible for very big outbreaks, especially in schools where numbers are associated together, and though it may exercise its morbid influence at any time, yet it selects the springtime most frequently, possibly because then the conjunctiva is rendered more susceptible by pollen and dust. But it must not be forgotten that the pneumococcus is associated with a condition very similar to that of the Koch-Weeks bacillus, not so acute, I think, as an attack that sometimes is produced by Koch-Weeks, but more prolonged and less inclined to yield and with more constitutional disturbance. The anxiety, too, lest the corneal epithelium should become eroded should be much greater with the pneumococcus.

Streptococcal infection is not common; these micro-organisms are found in membranous conjunctivitis, of the responsibility for which the Klebs-Löffler bacillus is suspected, though it is not always found. Plugging of the vessels is said to occur in connexion with this infection, and the only time I have myself ever detected distinct plugging of a conjunctival vessel was in my own case. I had removed from a baby's eye a piece of grass over three inches long that was doubled on itself and lay concealed at the top of the upper conjunctival cul-de-sac. From the history of the case the foreign body had lain there (I am speaking from memory) for five or six weeks, and there was a very free discharge of what appeared to be thick pus from the conjunctival sac. As I was engaged examining the child with its head between my knees in the usual way, a fly settled on my forehead and I raised my left hand to flick it away, when I touched my eye with my finger. I did not pay much attention to it, not thinking from the circumstances of the case that the pus was likely to be particularly malignant, but a few hours afterwards irritation began in the eye, and the next day it was severely inflamed and chemosed, suggesting the possibility of gonorrhœal infection. The following day a black line like a hair could be seen in the swollen conjunctiva of the lower lid, and when I first saw it in the looking-glass I thought it was a hair, as also did another ophthalmic surgeon who tried to wipe it away with a pledget of wool. I had a good deal of constitutional disturbance, swelling of the pre-auricular gland, and continual chemosis and ptosis. Cultivations were taken from the secretion, but not at once, and the result was practically negative, but this was not surprising, as I had been using regularly germicide lotions. It was some three months before my eye could be considered quite well. Now, on reflection I believe my case to have been one of what is called Parinaud's conjunctivitis, cases of which I believe I was the first to describe in this country, though I did not recognise them as such when I wrote the account. No English text-book at that time, so far as I know, had described the condition. No observation I have ever made has given me such satisfaction as this, and I hope

[1] Founded on a lecture delivered at Oxford to the candidates for the diploma in Ophthalmology.

you will allow me to quote the article in THE LANCET of Nov. 7th, 1903, describing what I then called septic conjunctivitis:—

> From time to time among private patients of the better class one sees cases of acute inflammation of the conjunctiva with great thickening of that tissue and marked enlargement of the papillæ of both upper and lower lids, resembling somewhat in this respect, only more so, a very acute follicular condition provoked by atropine; the inflammation is usually limited to the palpebral conjunctiva, but there is a tendency for it to pass round the fornices and to involve the ocular conjunctiva. There is free lacrymation and the discharge more serous than purulent. Ptosis, more or less marked, is present. There is generally tenderness or enlargement of the pre-auricular glands and a good deal of constitutional disturbance is present. The condition is generally limited to one eye. Ophthalmic surgeons of experience will, I think, at once recognise the affection I am attempting to describe, but those text-books that notice it are, as a rule, rather vague, and some, I believe, classify the condition under acute trachoma, with which disease, however, it has hardly anything in common. It yields slowly but with certainty to nitrate of silver, sulphate of copper, or, better still, to argyrol (20 per cent.) in the course of from three to eight weeks. It is only when treated by hot fomentations, cocaine, or tying the eye up (too often the case) that the affection becomes exaggerated and extends to the cornea, producing a "soppy" condition of that structure and sometimes small infiltrated ulcers towards its margin.
>
> I have for many years seen isolated cases of this form of conjunctivitis occurring, as far as my memory serves me, in the spring, summer, and autumn rather than in the winter. My reason for drawing attention to it now is the fact that this summer, at any rate in the Oxford district, there has been quite an epidemic of such cases. In two days recently I have seen three severe instances quite unconnected with each other. It would be interesting to know if this has been the experience of surgeons in other parts.
>
> The bacteriology of this affection should be interesting; it cannot be very contagious, for with only ordinary precautions it is limited to one eye. The train of symptoms suggest a septic origin, and I have sometimes imagined I could trace a connexion with mangy dogs or cats, but this is little more than speculation. Perhaps others will be able to define a cause with more authority.

Curiously enough, referring again to my own conjunctival attack, I may mention that after I had attended to the baby I went to a friend's house who kept several dogs, and especially examined one that was mangy. Perhaps, after all, the baby was innocent!

As may be surmised from the foregoing remarks, Parinaud's conjunctivitis has been attributed to streptococci and in some cases they have been found in connexion with it.

The Morax-Axenfeld diplobacillus produces a more chronic form of conjunctivitis and is very definitely associated with the conditions that used to be described as angular conjunctivitis, so-called from the fact that the skin at the internal and external angles of the palpebral fissure was very generally affected. Before the discovery of the diplobacillus I had closely investigated such cases in order to discover, if possible, the cause of the remarkable peculiarity, and I then attributed it to the influence of the lashes of the upper lid, which at the inner and outer angles (especially the outer) came in close contact and rubbed against the skin. In the centre of the lid this is not so much the case, partly from the greater projection forward of the lashes and partly from the protection of the lashes of the lower lid which are more abundant at the centre than at the extremes of the lid, and I had a drawing made of a case which illustrated very markedly the point, where the appearance of "soreness" at the outer angle exactly corresponded with the part rubbed by the very long lashes of the upper lid. I am still inclined to think that the observation was a good one and that the micro-organisms are aided in their morbid work by the chafing of the lashes. The same sort of superficial erosion may occur at the periphery of the cornea. The whole effect produced by the micro-organism is that of "soppy eye."

The gonococcus is one of the most dangerous organisms that attack the eyes, and is responsible for more actual blindness than any other one cause. With modern ideas of cleanliness and treatment the percentage of eyes lost from this cause has become much less, but there are still plenty of opportunities for reducing the rate largely. I am alluding, of course, to the form known as ophthalmia neonatorum, though one has to recognise that all cases of this condition are not due to the gonococcus; and, indeed, in all cases of gonorrheal ophthalmia there is a mixed infection.

Gonorrhœal ophthalmia is generally excited by direct infection, but it is also said to occur by metastasis, but of this I am not personally satisfied. So many sources of error come in that I do not think an absolutely confident diagnosis can be made of metastatic infection. That metastasis does occur, of course, is well known in the case of articular rheumatism and iritis, and I only express my doubt as regards the conjunctivitis due to this organism. One of the chief peculiarities of this bun-shaped diplococcus is that it actually invades the epithelial cells, and may also be found inside polymorphonuclear cells. It is peculiar to man, and the cultures are difficult to grow and quickly perish. The tremendous chemosis and swelling of the lids produced by this inflammation are a source of very grave danger to the cornea, ulceration of which is a very common sequela. The early symptoms might be common to other conditions, but, as a rule, within 24 hours the condition of the parts makes the diagnosis certain. There are, however, exceptions and sometimes one sees a mild form affecting mainly the fornices and, with injection, extending on to the eyeball. This, however, when it occurs is seen in the later stages of the primary urethral attack and represents a condition that is sometimes said to be metastatic. For my own part, I believe this to be an infection at a time when the system has gained a certain stage of immunity, and this leads me on to point out that, in my experience, vaccines of this micro-organism have been of great value in bringing relief, and I should certainly advise you to use this form of treatment should occasion arise.

Just a word about treatment. I believe the keynote is cleanliness and masterly inactivity. Once the tissue has become infected nothing, I believe, tends to cure it but self-immunisation. I have so often seen meddlesome interference bring about the very condition that one would wish to avoid. I taught myself a lesson many years ago in this respect. I devised a lid-elevator which really was a hollow tube with a row of holes at its free edge communicating with a tube down the handle, on which I could place an indiarubber tube and flush out the conjunctival sac. This I did regularly several times a day, gently placing the lid-elevator underneath the upper lid. Notwithstanding the care I took, the whole of the conjunctival epithelium was shed, corresponding to the shape of the lid-elevator. Opposite to this place on the cornea ulceration took place. One must remember that the epithelium of the conjunctiva is swollen and soft and deeply infected and the salvation of the cornea depends largely upon its integrity. I think one should be satisfied with gently flushing the palpebral fissures and eyelashes and wiping therefrom any adherent discharge. One cannot get rid of the infection by flushing out the sac, and any good one may do in that direction is far more than counterbalanced by the damage to the epithelium that is occasioned thereby. Instillation of a drop of argyrol at intervals may be of advantage. Than this and general cleanliness I would suggest nothing more. If the pressure of the swollen lids becomes very great, division of the external canthus might be of advantage.

Leprosy, rare in this country, may infect the conjunctiva, when the typical bacillus will be found. You will remember that it was not found possible to grow this organism on artificial media, but recently[2] Mr. Moses T. Clegg has discovered a method of doing so.

I want to say a word or two about the staphylococcus aureus. It has not been credited with setting up conjunctivitis, but in a paper I read before the Ophthalmological Society of the United Kingdom last December I pointed out the condition of staphylococcus aureus infection of the Meibomian glands as associated with severe conjunctivitis, the attack arising when from one cause or another the resistance is lowered. In the cases I have seen there has been no great amount of discharge, but a very great degree of hyperæmia, with accompanying sense of dryness and soreness of the eye, producing an extreme degree of discomfort. In one case in particular, where the infection of the glands was very marked, and where the opening of the ducts showed as yellow spots along the lid margin and from which thick yellow discharge could be readily expressed, pure cultures of staphylococcus aureus were obtained. After expressing the discharge by pressure along the lid margin and treating with a vaccine made from his own micro-organisms, the attacks at once ceased. When treatment had been discontinued about a year there was a recurrence of the appearance. This lasted for some time until he had an opportunity of again undergoing the treatment, when the symptoms again promptly disappeared. A fuller account of this trouble will be found in the Transactions of the Ophthalmological Society of the United Kingdom for this

[2] THE LANCET, June 11th, 1910, p. 1641.

year and it is a cause of conjunctival infection that should certainly not be overlooked and seems clearly to implicate the micro-organisms discovered growing freely in connexion with it.

Now let me pass on to the diphtheria or Klebs-Löffler bacillus. This is frequently found in conjunctivitis when a membrane forms, but not always, though in cases where it is not found its presence may be suspected. At the same time we must not forget that almost all other forms of micro-organisms to which I have alluded are also found. The membrane is due to coagulation of the fibrin and probably represents a condition in which there is a freer exudation of blood plasma and not necessarily that the Klebs-Löffler bacilli must be present. We get a coagulation, too, sometimes after the use of a strong caustic. I suggest this may be due to precipitation of mucin rather than fibrin, but I only suggest this from the clinical appearance and also because it is a plausible suggestion. It used to be said that in true diphtheria of the lid no false membrane was formed, but the tissue of the lid became like a block of wood, whereas when false membrane formed it was called croupous. In these cases the membrane is easily peeled off, leaving a bleeding surface, and is not a source of special danger to the cornea, as is the case when the whole lid becomes indurated. I myself have never seen a case of induration of the lid without false membrane. Cases of conjunctivitis with false membrane are, of course, fairly common; judging from clinical experience alone, I should not expect to find that they were all true cases of diphtheria. However, this is extremely disputed ground, and beyond drawing your attention to the subject I do not propose to discuss it further. An interesting question here arises as to the differentiation between the Klebs-Löffler and the xerosis bacillus. Now the xerosis bacillus is always, I think, to be found in the conjunctival sac, whereas the Klebs-Löffler bacillus is only associated with membranous exudation and brawny infiltration of the lid; but to state this is, I think, to beg the question to which I wish to draw your attention. Is there any real difference between the Klebs-Löffler and the xerosis bacillus? They morphologically resemble each other and behave in the same way, only differing in a matter of degree, except in so far as their morbid influence is concerned, for whereas Klebs-Löffler bacillus has a most poisonous effect the xerosis bacillus is inert. But it is well known that malignant germs can be attenuated until they become innocent. How then can we say that the xerosis bacillus is not an attenuated form of the Klebs-Löffler? I do not think it is possible to make a judicial statement to this effect, though clinical symptoms support the view, which amounts to almost a certainty, that the two are distinct. The following case that occurred in my experience might lend support in either direction. Many years ago I was bicycling through Berkshire and stopped at a village inn for tea. The landlady drew my attention to a baby in a cradle with a bad eye. I looked at it and saw the typical condition which used to be described as croupous conjunctivitis. Nineteen years afterwards a young man came to the Oxford Eye Hospital having one eye blind with corneal leucoma and giving me the history that when he was a baby I had seen him at the village inn, and I at once recalled the incident. I suggested to my colleague, Mr. Adams, that he should tattoo the leucomatous cornea. The patient was taken into the hospital and he performed the necessary operation. There was a great deal of reaction and dense masses of false membrane formed on his eye for weeks, I am not sure it was not months, afterwards. When they were peeled off they were soon replaced, and this went on, as I have said, for a very long time; of course, it may have been a coincidence, but at any rate it was a very remarkable coincidence, and I suggest the possibility of the Klebs-Löffler bacillus having lain dormant in his conjunctival sac for 19 years ready to associate itself with the wounds in the cornea and conjunctiva, which was drawn over the cornea, resulting from the operation of tattooing.

In this connexion I may speak of trachoma. Its association with a specific micro-organism has not been established, though claims have been put forward. The subject is a very big one and must be dealt with by itself. There is no doubt that it is contagious, though I do not believe it is so to anything like the extent that it has been generally supposed. It is interesting to note among the writers of the first half of the last century how all sorts of conditions have been included under this heading. The interesting passage in Mackenzie's "Diseases of the Eye" (fourth edition, p. 437) describes an attack of trachoma in the slave-ship *Le Rôdeur* in 1819. This epidemic was obviously gonorrhœal ophthalmia, and such is doubtless the case with several of the attacks described among armies, but in these later days trachoma is narrowed down to a very definite entity associated with an appearance that it is hardly necessary for me to describe to you. I will only point out now what I have suggested before, that its contagiousness is not nearly so active as is supposed. Other conditions must, I think, have a very large share in the incidence of the attack. My experience in hospital work places me in a peculiar position for forming a judgment. I have been for over twenty years surgeon to the Oxford Eye Hospital, a country district, and at the same time for over ten years to the Royal Eye Hospital, Southwark. A case of so-called follicular conjunctivitis seen in London I would know would resolve itself, almost as a certainty, into trachoma. The same sort of case seen in the country I would be equally certain would recover completely without further symptoms. As a further illustration of this I may mention that in the workhouse at Abingdon, sleeping in a dormitory with a large number of other children, was a case of severe trachoma accompanied by pannus and free secretion. The case from its history had obviously been going on for a year, and yet not one of the other children was affected. Such a thing could not have gone on in a London workhouse school without general infection taking place. However, I will satisfy myself with throwing down this apple of discord in the presence of Mr. Stephenson, who probably knows more than anybody else in this country about trachoma.

I will pass on to conjunctivitis associated with follicles. Lymphoid follicles might almost be considered as a normal condition of the lid and are seen more often as even rows of translucent elevations near the fornix of the lower lid. They are sometimes enormously increased in number in conditions of lowered health like anæmia and cases of hypermetropia, perhaps arising from congestion due to the straining of the ciliary muscle, for marginal blepharitis often arises from the same cause. They are often associated with the local effect of atropine, eserine, or cocaine, but, when due to the irritation of these drugs, they are generally inflamed and constitute conjunctivitis. But they are frequently seen without any appearance of inflammation whatever and are, as I have suggested before, merely a hyperplasia of the normal tissue. When from any cause conjunctivitis does arise in cases where these are present, it presents especially severe symptoms, but by the inflammatory process the disappearance of the follicles is brought about in the process of recovery.

Now, a few words on localised conditions. There is the primary syphilitic chancre with its indurated margin which, when once well developed, is easily recognised, but which, in the earlier stages, is a matter of some difficulty, perhaps mainly because it is unsuspected. Tubercle shows itself as polypoid outgrowths of a granulation tissue, as small nodules, and as ulcers which tend to coalesce. The palpebral conjunctiva is usually affected, though not solely. Tubercle bacillus may be found, but often is not. It is well in cases where tubercle is suspected to observe von Pirquet's vaccine reaction. You will remember the other day I showed you a boy whose conjunctiva showed what seemed to be typical of one form of tubercular conjunctivitis. Yet the von Pirquet reaction was negative. This was to me of especial interest for, from the clinical appearance of the case, I had no doubt that it was a case of tubercle, but in the face of the negative reaction I cannot feel so certain. Yet I cannot suggest any cause that seems to me a probable one other than tubercle.

In connexion with tubercle it is well to draw your attention to the form of conjunctivitis that might suggest it as the cause, but is really excited by the hairs of certain caterpillars. The disastrous consequences that occur not only to the conjunctiva but to the deeper structures of the eye must be borne in mind.

Spring catarrh, a very rare condition in this country, is occasionally seen. Its etiology is very doubtful. The appearance, however, is typical. The conjunctiva within the lid margins shows new growth of the appearance of paving stones, or, as one of you suggested to me the other day, the mud at the bottom of a dry pond cracked by the heat of the sun. I think that is a more typical appearance than paving stones.

Another form of this trouble is when the bulbar conjunctiva is affected with a sort of brown, brawny infiltration surrounding the cornea near the limbus. Lately, Mackenzie Davidson has claimed to be able to cure such cases fairly rapidly with the aid of radium. The conjunctivitis associated with phlyctenules, herpes, and pemphigus is, no doubt, neuropathic in origin. The phlyctenular type presents marked injection of the bulbar conjunctiva, without or with very little conjunctival discharge. Sometimes there may be no phlyctenules, and the characteristic I have mentioned will suggest the condition. Herpetic vesicles on the conjunctiva are not very common, but they do occur, and give rise to a great deal of trouble. In connexion with herpetic vesicles on the cornea or conjunctiva or skin, it is interesting to note that you always, I think, find enlargement of the auricular glands, suggesting from that symptom alone that the cause might have been micro-organisms; but this is only an instance of how wrong conclusions may readily be drawn, and are so often drawn, from our insufficient knowledge of this new branch of medical research. It is obvious, I think, in this case, that the necrotic tissue formed at the seat of the vesicle has been an effective nidus for the growth of organisms which have in this way affected the lymphatic system. Phlyctenular conjunctivitis, though not due to tubercle, as has been very clearly shown by Mr. Stephenson, is frequently associated with it. The *causa causans* of pemphigus is more or less wrapped in mystery. Radcliffe Crocker suggests that it is due to the action of toxins on the nerve-centres. Be this as it may, the condition described as essential shrinking of the conjunctiva is doubtless a later stage of it. The condition of xerosis is often produced and xerosis bacillus found in it, but it is not at all probable that the trouble is originated by its presence.

I should mention the attacks of irritative conjunctivitis that occur in those who are liable to be irritated by the pollen of flowers, the intolerable "itching," and the desire to "tear the eyes out," the only real cure being to get away from the cause by going to the sea when the wind is not off the land. I have noticed that those who suffer from hay fever are often, though certainly not always, of the neurotic type, the same sort of people who get erythropsia after cataract extraction, and I have noted, too, that "hay fever" subjects are at other times particularly free from mucous secretion—people who do not soil their handkerchiefs much—and I have wondered whether the incidence of hay fever may not have something to do with insufficiency of the secretion of mucus. I throw this out as a suggestion but not as an established observation. One word in connexion with this subject upon a rare form of individual intolerance of certain flowers, not due probably to their pollen, I think, but to other characteristics. The two flowers that I have associated with patients are primulas and dahlias. It is an interesting type of inflammation which affects also the skin of the face something like erysipelas and the fact is well worth remembering.

I will just mention a conjunctivitis, a condition in which, however, the salient symptoms depend more on the corneal coaffection: it is that due to exposure to a naked arc light. The patient goes to bed apparently unaffected and after a few hours wakes up in intolerable pain from the shedding of the corneal and conjunctival epithelium.

In conclusion, I will say a few words about treatment. The main point in treatment is a "masterly inactivity." The infective condition gets well by a power of self-immunisation, not because you have irrigated the eyes with astringents. I kept statistics of a large number of cases treated with astringents, with boric lotion, and with plain water. The astringents came last, the boric lotion and water were about equal in time of recovery. The one exception to these general remarks is the diplobacillary infection which is promptly destroyed by sulphate of zinc. Sometimes the conditions relapse or may become chronic, immunity not being completely gained, and then stimulation seems to answer, more blood is brought to the part, old cells are cast off, and the micro-organism is more effectually dealt with by the leucocytes. Phlyctenular conjunctivitis only requires fresh air under all conditions and in all weathers; it rapidly gets well, but it seems impossible to secure this in the patient's own home, and talk as you will to the parents and do what you will to the child the cases go on for weeks. They just will not carry out instructions. I remember the case of a child in a good social position who for weeks and weeks suffered from all the usual train of symptoms, intolerance of light, &c., for whom I gave the usual instructions, regular healthy diet and to get out of doors twice a day for long periods. Eventually the family medical attendant took part against me and I, perhaps rather rashly, said, "Let me have the child in the hospital and I will undertake to cure her in three days." The child, however, went home practically well on the fourth day, and I had done nothing more than I had previously suggested.

Other local conditions will more or less suggest the line of treatment that should be adopted, and for particulars of the details of treatment I will refer you to the standard textbooks.

Cavendish-square, W.

INFLUENZAL MENINGITIS.[1]

BY FREDERICK E. BATTEN, M.A., M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.

Introduction.—Influenzal meningitis is probably a rare infection, but its rarity in the past is very likely due to the difficulty in recognition of the organism, and even at the present time it is by no means certain that the organism described in some cases as the influenzal bacillus is identical with that described by Pfeiffer. Until November, 1908, no known case of influenzal meningitis had occurred in the Hospital for Sick Children, Great Ormond-street. Since that date 5 cases of influenzal meningitis have been admitted into the hospital—1 in November, 1908; 1 in December, 1909; and 3 in the earlier months of 1910. Of these cases 4 patients have died and 1 has recovered.

CASE 1.—On March 11th, 1910, a female child aged 1 year and 2 months was admitted to the hospital under my care. She was the second of two healthy children, the mother and father being quite healthy. There had been no miscarriage. The child had been quite well till Feb. 23rd, when the mother noticed that she was feverish and that the head was retracted. She had been under the care of a medical man for 14 days before being brought to the hospital, and at times had seemed better and at other times worse. She had never been unconscious, nor had she had convulsions. She had taken her food well, she had not vomited, and the bowels had acted regularly. On admission the child was quite conscious, well nourished, lay quite still if undisturbed, and apparently saw well. No change was noted in the fundus. The head was somewhat retracted, and the neck muscles were rigid, but there was no arching of the back and the limbs were not spastic. The fontanelle was prominent. The temperature during the first five days varied from 101° to 103° F. The knee-jerks were active, the plantars gave an extensor response, and the abdominal reflexes were not obtained. Kernig's sign was not present. Lumbar puncture yielded a very turbid fluid which flowed out under considerable pressure. It contained a considerable amount of albumin, and on cytological examination the cell deposit was composed almost entirely of polymorphonuclear cells, among which both extra- and intra-cellular organisms were found. On culture a very scanty growth of diplococci resembling meningococci was found. The child was then treated with injections of 10 cubic centimetres of antimeningococcal serum of the Lister Institute, repeated every day for six days, but without effect. On March 12th Dr. J. Graham Forbes reported that the organism present in many respects resembled the bacillus influenzæ. A subculture was planted, and on the 14th he presented the following report:—

> The cerebro-spinal fluid is turbid, yellow in colour, and yields, of course, granular clot. There is a heavy deposit of albumin, and dextrose is absent. There is a dense cell deposit, composed chiefly of polymorphonuclear cells. Scattered groups of bacilli are present, some in diplococcal form, intracellular, and Gram-negative. There is no visible growth on serum, but films taken from the surface of the serum show numerous bacilli of variable length, some in diplococcal form, and all Gram-negative. Subcultures on blood agar show an abundant growth of bacillus influenzæ.

The growth and cerebro-spinal fluid were now submitted to Dr. J. A. Arkwright at the Lister Institute, who reported that 5 cubic centimetres of the cerebro-spinal fluid injected intravenously into a rabbit produced no effect. The growth of one

[1] Notes of a lecture delivered at the Hospital for Sick Children, Great Ormond-street, on May 19th, 1910.

blood agar tube was also injected intravenously into a rabbit without effect. A guinea-pig was injected intraperitoneally with the cerebro-spinal fluid and another injected intracerebrally, and a mouse subcutaneously with large doses of the culture without effect. It is therefore evident that the organism was not pathogenic to animals.

Having arrived at the conclusion that the organism was not the meningococcus and was in all probability the bacillus influenzæ, the injections of antimeningococcal serum were stopped, and having in mind the recent observations of Crowe, 10 grains of urotropin were given every four hours. The child took the drug well, but the temperature did not fall to normal till March 25th. The organisms could still be cultivated from the fluid on March 22nd, but on April 8th, when the next lumbar puncture was performed, the fluid was clear, contained a fair number of lymphocytes, a few polymorphonuclear cells, and was sterile.

The temperature was normal on March 28th, and the child seemed much better, but took but little notice of her surroundings. On the other hand, she heard well, said a few words, and knew her mother. On May 18th she could feed herself, but could not sit up in bed alone, and could not stand. She could not see, the pupils reacted to light, but not very actively, and there was no ophthalmoscopic change. With regard to the ultimate fate of the mental condition of the child I think it is impossible at the present time to foretell. That she may yet recover her sight is possible, for I have seen a child who, though blind for four months after an attack of meningococcal meningitis, yet recovered perfect vision. Since the above note was written the child has partially recovered sight and can now sit up and stand alone.

Four other cases of influenzal meningitis have been in the hospital under the care of my colleagues, Dr. A. E. Garrod, Dr. A. F. Voelcker, and Dr. W. S. Colman, to whom my thanks are due for permission to refer to them. The first case was admitted to the hospital on Nov. 25th, 1908, under Dr. Colman's care.

CASE 2.—The patient, a female child 6 months old, was quite well until four weeks before admission, when she had ear discharge. On Oct. 21st there was some retraction of the head and the eyes were turned up. On the 24th the child presented some signs of pneumonia. On Nov. 11th she became drowsy and there was twitching of the right arm. She was admitted to the hospital on the 13th. On examination she was a well-nourished child and was quite conscious but drowsy. All the limbs were stiff, and Kernig's sign was present. A lumbar puncture was performed and three drachms of fluid were removed. Dr. Forbes reported that the fluid was clear, containing a soft flocculent clot and small shreds of lymph. The majority of the cells were polymorphonuclear and a scanty number of diplococci were seen resembling the pneumococcus. On the 14th the child was unconscious. On the 17th twitching of the left side commenced, and on the 19th there was twitching of all the limbs. A further lumbar puncture was done and Dr. Forbes furnished the following report:—

> The cells are polymorphonuclear and short cocci are seen, some of which are in pairs. On culture a very short Gram-negative bacillus, presenting some coccal forms and occurring in pairs, was observed. Some long bacilli were also present. This organism is probably the bacillus influenzæ.

On Nov. 20th the child was injected with a vaccine of 25,000,000 organisms. On the 24th a further injection was given of half this number, but no improvement took place and the child died on the 25th. There was no necropsy.

CASE 3.—The third case of this group of five cases is that of a male child, aged 7 months, who was admitted under the care of Dr. Voelcker on Nov. 29th, 1909. The child had been quite well till Nov. 27th, when he was taken ill with a fit and had retraction of the head whilst lying in his mother's arms. The next day the child vomited and the fontanelle was noticed to be prominent. On the following day he was admitted to the hospital. The neck was rigid, the fontanelle was prominent, and the child was drowsy, but there was no rigidity of the limbs and Kernig's sign was absent. The patient evinced no sign of pain. There was no squint, the pupils reacted well, and there was no neuritis. The knee-jerks were active and equal, and the plantar response on the left was extensor and on the right no response was obtained. Lumbar puncture yielded a turbid fluid containing a thick viscid flake of purulent lymph. Dr. Forbes reported that the fluid contained albumin and a trace of dextrose. The cells composing the lymph were chiefly polymorphonuclear. A small number of Gram-negative organisms were seen. Culture on blood serum yielded a scanty growth of small Gram-negative bacilli resembling Pfeiffer's bacillus influenzæ. On Dec. 4th an injection of a vaccine of 2,500,000 bacilli influenzæ was made, and on the 6th and 7th the child seemed better. The cerebro-spinal fluid on the 7th had the same characters as on the first occasion, and a pure culture of bacillus influenzæ was obtained. The organism was both free and intra-cellular in the cerebro-spinal fluid. On the 8th a further injection of vaccine was given. On the 13th the child was worse; he had conjugate deviation of the eyes to the left, and died on that day.

At the necropsy thick pus was found covering the whole of the cerebral hemispheres and surrounding the spinal cord. All the other organs were normal.

CASE 4.—The fourth case was that of a female infant, aged 7 months, who was admitted under the care of Dr. Garrod on Jan. 27th, 1910. She was quite well till Jan. 14th, when she vomited continuously for two days. After one week she became dull and the temperature varied from 101·5° to 99·5° F. On examination she was found to be a well-nourished child. The anterior fontanelle was open, the head was retracted, and there was a marked Kernig sign. The knee-jerks were present. Lumbar puncture showed a turbid fluid, which on examination yielded a coarse clot with numerous slender Gram-negative bacilli and a very scanty growth of bacilli resembling bacillus influenzæ. On the 29th an injection of a vaccine of 5,000,000 influenzal bacilli was given. On the 31st the child seemed better, but on Feb. 1st she developed convulsions, the head became more retracted, and she died on the 4th.

Dr. Forbes's reports on the cerebro-spinal fluid were as follows:—

> Jan. 27th: The cerebro-spinal fluid is turbid and forms a clot; there is a heavy cloud of albumin, dextrose is absent, and there is a marked excess of polymorphonuclear cells, numerous small, slender Gram-negative bacilli resembling bacillus influenzæ. The culture was sterile.
> Feb. 1st: Numerous bacilli resembling bacillus influenzæ. A scanty growth of bacillus influenzæ.

No necropsy was obtained in this case.

CASE 5.—The last case of this group was that of a child aged 1 year and 4 months, who was admitted on Feb. 13th, 1910, under the care of Dr. Voelcker. Sixteen days previously to admission the child developed a cold, and six days later had a fit, during which the face, the arms, and the legs twitched; a similar fit affecting the left side occurred on the next day. Since then the fits had become more frequent. On admission the child was pale but well nourished; the temperature was 101·4° F. There was slight retraction of the head, and the neck was stiff. The patient was blind, and the eyes were constantly deviated to the left. The optic discs were pale. Both arms were rigid, and the legs were fully extended. The knee-jerks were present. On the 14th severe convulsions came on and the child died.

A post-mortem examination was performed on the following day, and on examination of the brain the whole of the anterior part of the cerebrum was found to be covered by a layer of pus, which also extended over the base. The ventricles also contained pus. The posterior surface of the cord was also covered with pus. On the anterior aspect of the body of the third dorsal vertebra was a small abscess cavity containing thick yellow pus. The pus and fluid from the cerebral ventricles and meninges were examined. The films showed numerous bacilli of varying size and length which were Gram-negative and resembled the bacillus influenzæ. On culture a pure growth of the bacillus influenzæ was obtained.

Symptomatology.—From a consideration of the cases just recorded it is possible to obtain a clinical picture of the disease. The symptoms are exactly similar to those which occur in the meningococcal forms of meningitis. In fact, it is impossible on clinical grounds alone to distinguish an influenzal meningitis from a meningococcal meningitis. Neither the acuteness of the onset nor the character of the symptoms nor the duration of the disease will in any way serve to differentiate these conditions. It is only possible to arrive at the diagnosis of influenzal meningitis by a careful bacteriological examination of the cerebro-spinal fluid obtained by lumbar puncture, and the cases just recorded would easily have escaped recognition except for the careful

examination of the cerebro-spinal fluid conducted by Dr. Forbes.

Historical.—Cases of influenzal meningitis have been reported from the year 1892, some three years after Pfeiffer had discovered the organism, but owing to the difficulty of identifying the organism and the presence of other organisms it is doubtful if any case can be accepted as influenzal meningitis before those recorded by Fraenkel in 1898—who found the organism in two cases of meningitis in infants. Slawyk in 1899 is stated to have been the first to establish the diagnosis of influenzal meningitis during life by means of lumbar puncture. Since that time several cases have been recorded.

An extremely good digest on this subject is given by Cohoe, who has collected 26 cases which he accepts as undoubted influenzal meningitis. He points out that since a precise diagnosis is only possible by a bacteriological examination of the cerebro-spinal fluid, the reports of many of the earlier cases are worthless in a statistical study of the disease. Of the 26 cases 14 (56 per cent.) occurred in children under one year of age, all of whom died, and the mortality for the whole series was 85 per cent. Langer records the case of a boy, aged 9 years, who recovered, which is the youngest age at which recovery has taken place. Douglas in 1907 recorded a case of influenzal meningitis in an infant, aged 10 months, who died on the eighth day, and Dudgeon and Adams in the same year recorded another fatal case in an infant also 10 months old. Mya, Bertini, Jundell, and Fraenkel have all reported cases in infants. These 14 cases, together with the 5 here recorded, give a total of 19 cases in children under 2 years of age—18 of these patients died and 1 recovered, giving a mortality of 94 per cent.

Diagnosis.—The essential difficulty in the diagnosis of these cases is the recognition of the organism. Unless routine cultures are made on some blood medium the organism may be easily overlooked and the fluid reported as sterile. In the present series of cases Dr. Forbes, in his reports states that both morphologically and culturally the organism has all the characteristics of the bacillus influenzæ, and Dr. Arkwright in one case has shown that the organism is not pathogenic to animals. Cohen has described an organism which he says has been confused by former observers with the Pfeiffer bacillus, which it resembles most closely morphologically and in staining reaction, but which is pathogenic to guinea-pigs and rabbits and against which it was possible to vaccinate an animal and obtain an antitoxic serum. The organism present in the first case reported cannot have been of this nature, for it was shown not to be pathogenic to animals.

The symptoms produced by influenzal meningitis in infants do not differ from those which are present in meningococcal meningitis, and the diagnosis of influenzal meningitis from other forms depends upon the bacteriological examination of the cerebro-spinal fluid. The cerebro-spinal fluid obtained by lumbar puncture may in some cases of influenzal meningitis be somewhat viscid, and such an observation may suggest the possibility of an influenzal infection. It can, however, hardly be regarded as a point on which alone the diagnosis could be made.

Treatment.—Lumbar puncture has been performed in most of the cases recorded, but it can hardly be regarded as a therapeutic measure, although recovery has followed this procedure in some cases. In the case under discussion the child was for six days treated with the anti-meningococcal serum of the Lister Institute, as the case was at first regarded as one of meningococcal infection. When the nature of the infection was recognised the serum was stopped, and 10 grains of urotropin were given every four hours for three weeks. The *rationale* of the administration of urotropin is based upon the observation of Crowe, "that after doses of urotropin within therapeutic limits a sufficient amount of the drug appears in the cerebro-spinal fluid to exercise a decided inhibitory effect on the growth of organisms, and will markedly defer, and in some cases prevent, the onset of a fatal meningitis." The favourable result obtained in this case cannot with certainty be attributed to the treatment with urotropin, but the fact that all other cases of this nature in children under two years of age have proved fatal, whereas this child recovered, makes the treatment worthy of further trial.

Conclusion.—Although the cases above recorded differ somewhat in the degree to which the bacteriological examination has been carried, yet they may all be accepted as cases of influenzal meningitis. The diagnosis of an influenzal meningitis must depend solely upon the bacteriological examination, for it is impossible clinically to distinguish influenzal meningitis from other forms of meningitis. In the only case of recovery which has taken place in an infant urotropin was given in large doses, and it would seem that this treatment is worthy of further trial.

Harley-street, W.

A COMPARISON MADE BETWEEN THE SIMPLE GASTRO-CIRCULATORY SEIZURE AND THE ANGINA PECTORIS ATTACK.

BY WALTER VERDON, F.R.C.S. ENG.

"THE symptom-complex called angina pectoris belongs to the class of reflex protective phenomena." So writes Dr. James Mackenzie in his work upon Diseases of the Heart, after putting forward a reasoned argument in favour of the view that angina pectoris is a cardiac reflex.

In the course of this article evidence opposed to the latter inference is laid before the reader, and proofs are adduced tending to show that the anginal seizure is a gastric reflex, that it is evolved from the painless type of simple gastro-circulatory seizure, and that the entity pain is not an essential content of the syndrome but an excrescent appendage. Much attention is bestowed by writers on angina pectoris in the investigation of the pain symptom, while other symptoms holding a constant place among the contents of the syndrome are allowed to pass unnoticed. By this attitude on the part of observers I am reminded of the tale of the student who, when asked by his examiners to describe an operation, spoke only of the extent of the hæmorrhage. In the anginal attack there is much else worthy of consideration besides pain. Indeed, if pain be eliminated altogether from the field of contemplation the symptoms remaining are observed to constitute a complete and harmonious category.

When the anginal attack is considered in regard to its place among paroxysmal seizures, it is found to resemble a class associated with functional disorders of the stomach, of which the simple gastro-circulatory seizure commonly known as a vomiting attack is a strong example. The dual syndrome of the simple gastro-circulatory attack represents a series of operations organised for the purpose of protecting the stomach from the effects resulting from the intrusion of a noxious body. The gastric group of operations have for their object neutralisation of the offensive properties of the irritant and its ejection from the gastric cavity; the circulatory group the defence of tissues of the gastric wall and the repair of its lesions.

The gastric operations are divisible into three groups—namely: (*a*) Operations for furnishing a direct and open path between the cavity of the stomach and the exterior of the body for the rapid discharge of the gastric contents. These operations are accompanied by an abundant flow of saliva to dilute and neutralise the contents of the stomach and to lubricate the passages. (*b*) Operations for the provision of a firm and fixed diaphragmatic cushion against which the stomach may be compressed. (*c*) Operations determining the compression of the stomach against the inflated diaphragmatic cushion, and the ejection of the gastric contents.

The circulatory syndrome represents operations engaged in with the object of counteracting the effects produced on the tissues of the gastric wall by the presence of an irritant body in the stomach. These operations consist of two groups:—1. The provision of an abundant supply of blood to the splanchnic region. 2. The establishment of compensatory constriction of the stream bed in the somatic and thoracic regions.

When the gastric crisis approaches, as that arising from

the presence in the stomach of an irritant, the stream bed in the splanchnic region undergoes augmentation and furnishes accommodation for a large additional influx of arterial blood. Precisely the same thing happens in the case of a limb or other organ under irritation or lesion. The purpose of the operation is to supply the affected region with nutrient fluid and leucocytes in abundance for the means of repair and for the requirements of defence. The purpose of constriction of the stream bed of the somatic and thoracic regions is to hasten the current of the arterial blood stream in the direction of the scene of irritation and to maintain the standard elevation of general systemic blood pressure which would otherwise fall to a level so low as to endanger the integrity of all circulatory processes.

Schema A.

In this table the gastric and circulatory operations which take place to counteract the presence of an irritant in the stomach are enumerated in the first column, while in the second appear the symptoms representing these operations.

The Gastric Syndrome.

(*a*) *The establishment of a free, open, and direct œsophageal path for the outward passage of the gastric contents and the abundant secretion of saliva for the purposes of dilution and lubrication.*

Operations.	*Symptoms.*
Dilatation of vessels distributed to lacrymal, nasal, buccal, pharyngeal and submaxillary glands exciting a flow of secretion for the purpose of lubricating the passages.	Free flow of saliva and watery fluids into the mouth and pharynx.
Coördinated action of mylohyoid, hyoglossus, and other pharyngeal and laryngeal muscles for the purpose of opening and straightening the passage, and for conveying saliva into the œsophagus and stomach.	Swallowing movements.
Contraction of fibres radiating from the cardiac end of the œsophagus, thus opening the lower end of this tube, associated with inspiratory efforts distending it with air. Hypertension of gastro-mural muscle.	Retching.

(*b*) *The provision of a firm and fixed diaphragmatic cushion.*

Operations.	*Symptoms.*
Deep inspirations.	Attempts at deep inspiration.
Closure of the glottis.	Laryngeal spasm.
Fixation of diaphragm.	Inability to take deep breaths.
Fixation of thoracic muscles.	Sensations of tightness and constriction of the chest.

(*c*) *Compression of the stomach against the fixed diaphragmatic cushion and the ejection of the gastric contents.*

Contraction of the gastro-mural muscle.	Sense of gastric tension. Eructation of flatus.
Spasmodic and violent contractions of abdominal muscles.	Vomiting.

The Circulatory Syndrome.

(*a*) Vaso-dilatation in the splanchnic region.	Fall of blood pressure, faintness, pallor, coldness of the skin, small pulse, shrunken veins, feeble beat force, slow pulse-rate, irregular rhythm with intermissions or extra systoles, abundant flow of pale urine.
(*b*) Compensatory vaso-constriction in the somatic and thoracic regions.	Rapid pulse rate, constricted arteries, sweating.

The circulatory syndrome occurring in the simple gastro-circulatory attack corresponds with the period of nausea and faintness which precedes the act of expulsion of the gastric contents. When the medullary centres of the gastric mechanism are in a robust state the duration of this period is exceedingly short and may pass unnoticed. When these centres are sluggish, as in many forms of dyspepsia, it is prolonged for many minutes or even for one or two hours. It sets in with a falling blood pressure. The shifting of the bulk of the blood stream from the somatic to the splanchnic region leaves the surface arteries and veins alike empty. The pulse is soft, irregular, and intermitting. The skin is cold and pallid, withdrawal of blood from the medullary centres and brain leads to perverted sensations, abnormal cardiac action, disordered breathing, a sense of giddiness and faintness, and even total insensibility.

When compensatory vaso-constriction is feeble these symptoms are exaggerated. When spasmodic and local they may be found associated with hard tight arteries and a thread-like pulse or other evidences of vaso-constriction. The series of cases now cited represent the gastro-circulatory attack in several of its phases.

CASE 1. *Dr. X.'s experiences.*—"It was the custom in a school at which I received my early education for the boys to run at a jog trot pace several times round an enclosed space just after a full meal of milk and bread and butter. During the final lap or before this stage in the course had been reached I often found my breath to be giving out and when I could go no further I used to throw myself down and remain full length upon the turf until my breath returned. On these occasions I experienced sensations of faintness, breath hunger, giddiness, and throbbings at the chest, and sometimes hiccough and retching. On account of many of my school fellows suffering in like manner as myself, representations were made to the house master and orders were given for the meal to be served after the run instead of before it. Under the new rule attacks of this kind seldom occurred."

CASE 2. *Newspaper reports.*—Death of a girl, aged 17, at a skating rink, May 4th, 1910. Medical evidence showed that death was due to heart failure caused by exercise following a rather heavy meal.

CASE 3. *The experiences of a chronic dyspeptic.*—"On March 10th, 1910, when leaving Victoria Station on my way to the Strand no sign of gastric or circulatory disturbance was noted. My way lay along Victoria-street, and when the Army and Navy Stores were approached feelings of gastric distension and a desire to eructate flatus declared themselves. These sensations were ignored and the walk was continued until the porch of the Westminster Palace Hotel came in sight. I then experienced a distressful sensation in the chest, painless in character, but like that of 'lost breath' or 'air hunger' felt during an exhausting race; my muscles refused to carry me forward. The pulse was small and feeble, with a beat rate of 96 per minute. It was interrupted by frequent intermissions. The veins on the dorsal aspect of my hands, usually of large calibre, were shrunken to threads. While still halting I retched several times and succeeded in dislodging a considerable volume of flatus from the stomach. The sensation of distension relieved, the pulse again began to run an even course without intermissions. No further signs of circulatory disturbance manifested themselves before my destination was reached."

CASE 4.—Recently a chronic dyspeptic gave me the following account of his experience:—"After a meal of sandwiches and ale I contested an impromptu race. The course lay on a steep incline crowned by a long flight of stairs. Gaining the lead in the first 200 yards, I retained it, and, mounting the stairs without halting, I reached the summit alone. But no sooner had I come to a standstill than everything seemed to be swimming round me. My sight became dim, and, unable any longer to keep my feet, I sank to the ground in a semi-conscious state gasping for breath. Here I lay for several minutes feeling much oppressed at the chest, but upon bringing up a large quantity of flatus I soon began to recover, and felt quite well again in 10 or 15 minutes."

CASE 5.—A type of attack presenting a gastro-circulatory syndrome somewhat similar in character to those already cited sometimes occurs during a period of profound rest. Mrs. M., who had sought my advice on account of the occurrence of certain obscure and alarming attacks from which she had suffered occasionally, stated that on the evening before she had gone to bed at 11 o'clock feeling quite well. Between 12 and 1 o'clock she was awakened from sleep by a feeling of oppression about the chest as if there were a weight upon it intolerable to bear. "I sat up in bed," she said, "and could not take a deep breath as my chest was tightly bound as if gripped in a vice. What little inspiration I was able to make was accompanied by a crowing sound in the throat. My attendant slept in the next room and I tapped on the wall with the object of obtaining her assistance. I thought I was dying. When she came to me breath was entering my chest more freely but I still felt very ill. I was icy cold, my mouth was full of frothy slime, and my pillow was wet with saliva. I gulped up some wind from the stomach and then lay down feeling relieved. I had uncomfortable feelings about the stomach accompanied by rumbling sounds, but I was now able to breathe freely and I had no longer the terrors before me of approaching death. The attack lasted about two hours and then subsided. Afterwards I went to sleep and slept soundly until morning."

The attendant, who is an intelligent trained nurse, gave me the following account of the attack. "When I entered Mrs. M.'s room I thought she was dying; her face was dusky white, her features were pinched and bathed in perspiration, her hands were cold. I could not feel any pulse at first, and when I found it it was small and feeble, sometimes it stopped beating altogether, and then went on again. I did not notice anything unusual about the patient's breathing. I gave her some brandy; after drinking it she brought up wind several times and her appearance improved. When I again felt her pulse it was beating rapidly with occasional intermissions; later the pulsations at the wrist became quite normal. She complained several times of the rumbling of her stomach, and the sound of it was sufficiently loud to be heard across the room; no vomiting occurred, nor did she complain to me of feeling sick or of any pain."

During the course of the previous six months Mrs. M. had suffered from many attacks of a like character, sometimes coming on in the daytime but generally at night. As far as I could ascertain, her diet was of the simplest description, nor upon the day or evening preceding this attack did she eat or drink anything out of the common course. The patient presented no signs of organic disease. The attacks ceased altogether after milk, which was often taken at bedtime, had been eliminated from her dietary.

CASE 6.—Mr. A., who had been known to me for some years as a gross eater, went to bed one night after a late dinner apparently in the enjoyment of good health. At 2 o'clock on the following morning I was called to see him. His face was pallid and bathed in perspiration. His hands were pale, cold, sweating, and shrunken, and the veins at their dorsal aspect were represented by tiny blue threads. His pulse was small, feeble, rapid, and interrupted at every few beats by intermissions. He occasionally yawned, hiccoughed, swallowed saliva, and retched, and saliva was noticed to trickle from the corners of his mouth and had already wet the covering of his pillow and the front of his night shirt. He was squinting and the muscles of his face twitched. He was not conscious of my presence. His pulse upon a second examination was almost imperceptible, his breathing became shallow

and irregular, and a snoring whistling sound was heard with each laboured inspiration. He had sunk down in bed, his head was flexed on his neck, and his chin rested on his chest.

The pillow and bolster were removed and his head was drawn over the side of the bed and depressed with the double object of encouraging a flow of blood to the medullary centres and a better supply of air to the lungs. At the same time my fingers were forced into his throat to discover if any lodgement of food had taken place in the neighbourhood of the aperture of the glottis. While my fingers were still in his throat he gulped up a large quantity of gas. Convulsive vomiting efforts followed, resulting in the expulsion of half a gallon of dark fluid mixed with undigested food. Ten minutes later the patient was sitting up in bed, and in answer to an inquiry said he felt quite well.

When attacks such as those endured by Mrs. M. and Mr. A. result in the expulsion of the contents of the stomach by vomiting, the purpose underlying the symptoms becomes manifest.

Having now examined and tabulated the processes and symptoms occurring in the painless type of the simple gastro-circulatory attack, we are in a position to approach the consideration of the painful type—namely, angina pectoris—to hold up for comparison all that appertains to these two types of seizure.

When the anginal seizure is stripped of its pain symptoms, the symptoms remaining may be divided into two categories, a gastric and a circulatory, and each of these differentiated groups is observed to stand alone as a complete organic entity, while together they form a dual syndrome. Each section of the dual syndrome represents a purpose, and processes in operation for carrying the purpose into effective consummation. So every symptom in the contents of the respective syndromes is a sign or outward manifestation of a process of the gastric or circulatory mechanism working towards a definite and determinate end.

If the syndrome of the gastric and circulatory symptoms of the anginal seizure be examined closely they are observed to afford evidence of the existence of processes in operation, animated by purposes precisely similar to those manifested in the dual syndrome of the simple gastro-circulatory attack. There is this difference, however, between the two types of seizure. In the robust forms of the simple gastro-circulatory attack the processes in operation as represented in the gastric section of the dual syndrome are perfectly coördinated and sufficiently effective to accomplish their end, and the attack terminates in expulsion of the contents of the stomach; whereas in the case of the anginal seizure the processes in all their operations are inefficiently organised and abortive, and the purpose of the seizure usually remains unfulfilled.

Every entity in the contents of the gastric section of the dual syndrome of the anginal seizure is then to be regarded as a feeble or exaggerated reflexion of a symptom having a place in the corresponding syndrome of the robust forms of the simple gastro-circulatory attack. It therefore follows that while the purposes and the operations manifested in the parallel syndromes are alike in their nature and essence, the presentations of these operations in the respective seizures are dissimilar.

A significant illustration of this unity of purpose and operation and inequality in presentation, furnished by the two types of seizure, is observable in a well-defined group of symptoms—namely, that which represents the operations of the gastric mechanism having for its object the formation and fixation of a firm diaphragmatic cushion against which the stomach may undergo compression during the final act of vomiting. This end is attained to perfection in the robust form of simple gastro-circulatory attack, while in the anginal seizure the accomplishment of the same purpose is attempted by imperfectly coördinated efforts.

The processes engaged in the operation are as follows: (*a*) Inflation of the chest with inspired air; (*b*) closure of the aperture of the glottis; and (*c*) contraction and fixation of the diaphragmatic, intercostal, thoracic, and cervical muscles. For the purpose of comparison the operations occurring in the simple gastro-circulatory attack and the symptoms presented in the anginal seizure are placed side by side in parallel columns.

A group of operations occurring during the simple gastro-circulatory attack.	*A corresponding group of symptoms presented during the anginal seizure.*
(*a*) Inflation of the chest with inspired air.	"*The patient has to stand still and take a great deep inspiration.*" (Mackenzie: Diseases of the Heart, p. 46.)
(*b*) Closure of the aperture of the glottis.	"*There may be laryngeal spasms.*" (R. Quain: Dictionary of Medicine, p. 53, 1882.)
(*c*) Contraction and fixation of the diaphragmatic, intercostal, thoracic, and cervical muscles.	"*The breathing is disturbed, oppressed, and restrained.*" (Douglas Powell: Allbutt's System, vol. vi., p. 48.) "*The breathing is sometimes distressing although the patient can take a deep breath when asked to do so.*" (Bristowe's Medicine, p. 53.) "*A sense of constriction as though the heart was gripped or the thorax were severely pressed.*" (Douglas Powell: Allbutt's System, vol. vi., p. 47.) "*Feeling of great tightness over ribs.*" (Ross: *Brain*, vol. x., p. 355.) "*Pain is generally attended with a sense of constriction.*" (Bristowe's Medicine, p. 519.) "*Pain associated with a sense of constriction 'as if a mailed hand grasped the chest.'*" (Balfour: Twentieth Century of Medicine, p. 445.) "*Some would limit the term Angina Pectoris to that class of cases where in addition to the pain there is a sense of constriction in the chest, amounting to the sensation at times as if the chest were gripped in a vice. I am convinced that these sensations arise from spasms of the intercostal muscles.*" (Mackenzie: Diseases of the Heart, p. 38.)

Another series of symptoms may be observed in the anginal seizure which have a prototype in the simple gastro-circulatory, and in both represent processes in operation for diluting and neutralising the contents of the stomach and for opening, straightening, and lubricating the œsophagus. These processes consist in the secretion of an abundant flow of saliva, swallowing movements, and retching.

Dr. Mackenzie frequently mentions the abundance of the flow of saliva and describes the process of retching. His evidence is the more valuable because it is adduced in favour of a theory not in accord with my argument. It occurs in a statement to show the eructation of flatus which is a common symptom in angina pectoris is the result of "air swallowing." He writes: "Another symptom is extremely common in these cases" of angina pectoris—namely, "the belching of air. ..... Before expelling the air patients unconsciously close the glottis, fix the muscles of the abdominal wall, then expand the chest." "By this process they suck air into the stomach, after sucking in a quantity they expel it with considerable force."[1]

Compare this description of symptoms of an anginal seizure from Mackenzie with that of the simple gastro-circulatory or vomiting attack by Starling. "The act of vomiting is generally preceded by ..... copious salivation and retching. Retching is a violent inspiration while the glottis is kept firmly closed, so that air is drawn into the œsophagus and distends it. This stage is followed by contraction of the fibres radiating from the cardiac end of the œsophagus which opens and allows gas to escape."[2]

In the simple gastro-circulatory attack there is a third group of processes also represented in the anginal seizure—namely, those connected with the expulsion of food from the stomach. They consist of closure of the pyloric orifice, contractions of gastro-mural muscle, and compression of the stomach between the abdominal walls and the inflated cushion of the diaphragm. These processes are represented in the anginal attack by a sense of gastric tension, by forcible expulsion of flatus, and by vomiting.

Vomiting, as might be expected, is a somewhat rare incident in the anginal seizure where the processes of the gastric mechanism are imperfectly coördinated, but it is occasionally described as occurring. It is spoken of by Douglas Powell. "The patient vomits and becomes easier."[3] On the other hand, eructation of flatus is a common feature in every attack. Dr. Mackenzie says: "The case may end by expulsion of air from the chest."[4] "Eructation gives relief."[5] And, again, Mackenzie: "Another symptom is very common in these cases, the belching of air." "The

[1] Mackenzie: Diseases of the Heart, p. 55.

[4] Disease of the Heart, p. 47.
[5] Dr. Powell, Allbutt's System, vol. vi., p. 49.

chief feature is the noisy expulsion of air from the stomach."[6]

So far I have only spoken of the gastric syndrome, but the anginal attack, like the simple gastro-circulatory, has a dual syndrome—gastric and circulatory.

In the circulatory syndrome, as in the gastric, a purpose is discernible and the symptoms manifesting it present themselves in boldest outline when the seizure is prolonged. They appear in the period of faintness and pallor, and are contemporary with an influx of arterial blood to the splanchnic region and a withdrawal of the red stream from the somatic and thoracic areas. The same thing occurs in other regions of the body in the presence of an irritant. Local vaso-dilatation is always associated with general compensatory vaso-constriction, and the purpose underlying this disposition of the blood stream is the abundant supply of leucocytes and plasma for the protection and repair of the injured organs.

In the circulatory syndrome of the anginal attack the gastric crisis is a predominant factor, and the splanchnic vessels are the scene of great arterial activity, the outlying regions being drained dry of the stream. Every symptom in the syndrome bears witness to the determination of the greater bulk of the stream to the splanchnic field of distribution of the stream bed, and no sign is found existing in the course of the syndrome which opposes itself to an interpretation of the symptoms in accordance with this hypothesis.

The points of resemblance between the circulatory syndrome of the anginal attack and the corresponding syndrome of the simple gastro-circulatory are many and significant. In both there is a falling blood pressure, venous and arterial, although instances may occur in which blood pressure is sustained at a high elevation on account of organic constriction and obliteration of large circulatory tracts in the splanchnic region as in some forms of nephritic and hepatic disease. Moreover, a fall in blood pressure may be arrested and the movement in the mercury of the manometer reversed through the operation of vigorous compensatory changes in the stream bed, or by an augmentation in the driving force of the heart or an increase in its beat-rate.

In the anginal seizure, as in that of the simple gastro-circulatory, pallor, coldness, sweating, and other signs of depletion and attenuation of the somatic stream are in evidence. In both, moreover, symptoms are present pointing to a recession of the stream from medullary and cerebral centres, and even the heart itself shows signs of blood hunger and a variety of resultant disturbances. The incidence of compensatory vaso-constriction at a time when the heart and vessels of the upper part of the body are depleted of the red stream would tend towards the encouragement of spasmodic, crampy, and irregular contractions of cardiac and arterial muscle—a condition which in certain states of nerve centres and involuntary muscular fibre becomes a factor in the pain symptom. The spasmodic and patchy nature of the vaso-constriction impulse may be gathered from the following extracts.

Heberden reports a case of asphyxia of the left forearm and hand in which the extremity would suddenly become cold during the attack. Trousseau also reports a case where extreme pallor was followed by a pronounced violet and bluish colouration of the arm and hand, the natural colour being restored as soon as the pain ceased. Balfour records the case of a lady whose attacks were always preceded by pallor of the face and fingers, and Bristowe speaks of the affected limb becoming pale and cold. Douglas Powell relates a case where during the attack the pulse was very small, scarcely perceptible, but very hard and thready. In another case he speaks of the pulse being small and thready, and of a third he says: "An attack of pain came on attended with quickened action of the heart and diminution in size and increase in tightness of the pulse; the diminution in size proceeding almost to extinction, a mere tightened thread being felt under the finger." On the other hand, Mackenzie states that he has "never found a single case where the arteries were constricted in the manner sometimes described."

Angina pectoris, like the simple gastro-circulatory seizure, presents two prominent clinical varieties—namely, an attack coming on during exercise and ending upon the cessation of exercise; and a form of attack which generally begins in a period of rest and runs an independent course. Illustrations of these two clinical varieties are now given in the patient's (Dr. X's) own words.

CASE 7.—"On November 19th, 1909, I was called to visit a patient residing at a distance of a mile from my own door, and having at hand no means of conveyance for hastening the journey I set out on foot. My path lay along a road of easy and falling gradients and for the first hundred yards all went well with me. But soon afterwards I began to be conscious of discomfort at the præcordial region, and this sensation was accompanied by feelings of abdominal distension and a desire to expel gas from the chest. The præcordial uneasiness at length grew into pain, extending to both sides of the thorax and to the arms. The pulse had now begun to run rapidly, with intermissions at the end of every five or seven beats. It was small, feeble, and compressible. After a rest of a few minutes' duration, which brought relief, I continued on my way, but I had not gone more than seventy or eighty paces further when pain and sensations of gastric distension recurred and under the influence of rest or the expulsion of flatus again abated. These experiences were repeated several times before I came to the end of my journey."

The following account of an anginal attack is given by the same patient:—

CASE 8.—"On the morning of 7th March, 1908, while reading the daily paper after a breakfast consisting of a rasher of bacon, a few pieces of dried toast, and a cupful of coffee I became conscious of a dull aching pain at the chest. Afterwards, for a few seconds only did my mind continue centred in the news. For the pain, at first felt in the mid-line beneath the upper part of the sternum, was now extending upwards to the throat, finally to reach the molar region of the jaws, backwards towards the scapulæ, and laterally to the axillæ, elbows, and wrists. Moreover, every moment it was increasing in intensity.

The most extreme manifestation was focussed, and could be located, with some degree of exactitude, in the region lying behind the *manubrio-gladiolar synchondrosis*, while painful sensations of less magnitude continually radiated from this centre towards the back, neck, and arms. Pain did not extend below the plane of the diaphragm, neither was it accompanied by faintness, sickness, or embarrassment of breathing. The pulse was irregular, its rate was rapid enough to be beyond my powers of computation. The radial artery, usually full and strong, felt small and thread-like. The skin was wet with perspiration.

It is said that persons stricken by angina pectoris are distressed with forebodings of impending death. I am not conscious of having entertained any apprehensions of this character. My mind was clear and capable of concentrated thought. I considered the situation for a few seconds in expectation that the symptoms would pass off, but the pain gathering strength rather than abating I determined that something must be done quickly to obtain relief from my intolerable sufferings. At length I wrote a prescription for nitrite of amyl and sent it by messenger to a neighbouring chemist. The effort attendant upon this action greatly aggravated my sufferings. Neck and molar pain was intensified. Vision became affected. Objects seen at a distance across the room seemed to stand in a dark field surrounded by mist which rolled in eddies from centre towards circumference.

I had been in extreme pain for twenty-five minutes when the messenger returned, bringing with him a supply of nitrite of amyl capsules. Taking one, I crushed it and inhaled the vapour. Immediately I felt relief, which first reached the jaws, neck, and arms, and afterwards the chest. A sore feeling still remained in the substernal region which afterwards was removed by inhalation of fumes from a second capsule. Fifteen minutes later I was attending to the requirements of patients waiting to see me, and, except for some shakiness of the limbs, feeling no worse for my recent experiences."

The omission of any reference to gastric symptoms by the patient in the description of the latter attack does not imply their absence. Severity of pain during a seizure often obscures minor observations, and gastric symptoms in angina pectoris, although obvious to a bystander, are rarely commented on by the patient himself. In several attacks of a similar nature in the case of this patient I have been present, and have observed manifestations which are unmistakeably gastric in their origin.

Both forms of seizure are varieties of a type in which pain constitutes the most prominent symptom. The first cited differs from the second in the minor severity of its symptoms and in the frequency of its occurrence. Coming on when exercise is engaged in, its occurrence is exceedingly frequent, but since abatement of the seizure takes place on the cessation of exercise, its severity is but a faint counterpart of that of the other variety, which pursues its course to the end unaffected and unrelieved by rest. The first-named variety begins during exercise, is sustained by exercise, and subsides with the cessation of exercise, while the latter commences usually during periods of rest, runs a course independently of any apparent sustaining influence, and continues unrestrained, except under appropriate remedies, to its destined end.

CASE 9. *Description of the anginal attack by R. Quain.*[7]—An attack of angina pectoris commences suddenly with pain in the region of the heart, generally on a level with the lower end of the sternum. The pain is severe and of grasping, crushing, or stabbing character; it extends sometimes across the chest, but more frequently backwards to the scapulæ and upwards to the left shoulder and arm. The pain is accompanied by a distressing sense of sinking, of faintness, or of impending death. The action of the heart is generally irregular. The pulse at the wrist corresponds, but in some well-marked cases it is regular, tense, and resisting. A fear of aggravating the pain prevents

[6] Heart Disease, p. 55.

[7] Dictionary of Medicine, 1882, p. 51.

the patient from breathing, although the respiratory function may not be interfered with. The expression is anxious, the face is pallid, and the lips are more or less livid. The whole surface of the body is pale cold, and covered with a clammy sweat. Flatulence is often present, urine in some cases is passed at short intervals and generally in abundance. The sense of faintness causes the patient to seek support and he rests on any object by which this may be obtained. The attack having lasted for a variable time—from a few minutes to one or two hours—comes to an end, either by a sudden cessation of the more urgent symptoms or by their gradual disappearance.

Schema B.

Comparison of the symptoms of the painful type of the simple gastro-circulatory seizure with those of the painless.

Symptoms of painless type of simple gastro-circulatory attack.	*Symptoms of the painful type of gastro-circulatory attack or angina pectoris, observed by authors and recorded by them.*
Gastric Syndrome.	
(a) *Symptoms representing operations engaged in with the object of opening, lubricating, and straightening the œsophageal tube.*	
(1) Free flow of saliva.	"*Abundant flow of saliva.*" (Mackenzie: Diseases of the Heart, p. 39.)
(2) Swallowing movements.	*Swallowing movements.* "*Air-sucking and swallowing.*" (Ibid., p. 55.) "*Difficulty in swallowing.*" (R. Quain: Dictionary, p. 53.)
(3) Retching.	"*Eructation.*" (Mackenzie: Heart Disease, p. 47; Douglas Powell: Allbutt's System, vol. v., p. 48.) "*Flatulence is often present.*" (R. Quain: Dictionary, p. 51.)
(b) *Symptoms representing operations engaged in with the object of the establishment of a firm diaphragmatic cushion.*	
(1) Deep inspiratory act.	"*The patient has to stand still and take a great deep inspiration.*" (Mackenzie: Diseases of the Heart, p. 16.)
(2) Fixation of the muscles of the chest wall.	"*Pain associated with feelings of constriction as if a mailed hand grasped the chest.*" (Balfour: Twentieth Century of Medicine, p. 445.) "*Thorax compressed.*" (D. Powell: Allbutt's System, vol. vi., p. 48.) "*Sense of fixation of the chest walls.*" (Mackenzie: Diseases of the Heart, p. 45.) "*Fixation of the chest.*" (Whittaker: Twentieth Century of Medicine, p. 445.) "*Tightness across the chest.*" (Mackenzie: Diseases of the Heart, p. 45.) "*A sense of constriction independent of pain.*" (Ibid., p. 45.) "*Grips the chest, causing patient to take deep inspiration.*" (Ibid., p. 45.) "*Sense of contraction of chest.*" (Bristowe's Medicine, p. 519.) "*Feeling of great tightness over ribs.*" (Ross: *Brain*, vol. x., p. 355.) "*Cannot take deep breath.*" (Bristowe's Medicine, p. 519; Quain's Dictionary, p. 50.) "*Breathing oppressed and restrained.*" (D. Powell: Allbutt's System, vol. vi., p. 48.)
(3) Contraction of the diaphragm and muscles closing aperture of the glottis. Hiccough.	"*Diaphragm involved.*" (R. Quain, Dictionary, p. 50.) "*Laryngeal spasm.*" (Ibid., p. 50.)
(c) *Symptoms representing operations determining the expulsion of the gastric contents.*	
(1) Attack terminates in eructation of flatus.	"*The case may end by expulsion of air from the chest.*" (Mackenzie: Diseases of the Heart, p. 47.) "*Eructation gives relief.*" (D. Powell: Allbutt's System, vol. vi., p. 49.)
(2) Attack terminates in expulsion of gastric contents.	"*Patient vomits and becomes easier.*" (Allbutt's System, vol. vi., p. 49.)
Circulatory Syndrome.	
Painless type of simple gastro-circulatory attack.	*Painful type of gastro-circulatory attack (angina pectoris).*
(a) *Symptoms representing operations determining influx of arterial blood to the splanchnic region.*	
(1) Falling blood pressure.	"*Blood pressure falls during attacks.*" (Mackenzie: Diseases of the Heart, p. 47.)
(2) A copious flow of pale urine follows the attack.	"*A copious flow of pale urine.*" (D. Powell: Allbutt's System, vol. vi., p. 33.) "*Urine always pale, abundant, and of low specific gravity.*" (Mackenzie: Diseases of the Heart, (p. 47.) "*Urine passed in abundance.*" (R. Quain: Dictionary, p. 51.)
(3) Disturbance of beat-rate.	"*Pulse 120.*" (D. Powell: Allbutt's System, vol. vi., p. 50.) "*Pulse-rate slow.*" (Mackenzie Diseases of the Heart, p. 47.) "*Decidedly infrequent.*" (D. Powell: Allbutt's System, vol. vi., p. 48.) "*Heart often beats twice to one radial pulse.*" (Ibid.) "*Pulse 100.*" (Ibid.) "*Pulse rapid beyond computation.*" (Verdon: Heart, vol. i., p. 230.)
(4) Beat force feeble.	"*Beat force feeble.*" (Mackenzie Diseases of the Heart, p. 47.) "*Pulse weak.*" (D. Powell: Allbutt's System, vol. vi., p. 50.)
(5) Artery small	"*Artery small but no spasmodic contraction.*" (Mackenzie: Diseases of the Heart, p. 47.) "*Pulse scarcely perceptible.*" (Bristowe's Medicine, p. 520.)
(6) Rhythm irregular; intermissions.	"*Rhythm irregular, intermissions.*" (Mackenzie: Diseases of the Heart, p. 47; D. Powell: Allbutt's System, vol. vi., p. 50.) "*Action of heart irregular.*" (R. Quain: Dictionary, p. 50.)
(7) Constricted veins.	"*Constricted veins.*" (Verdon.)
(8) Pallor.	"*Pallor.*" (D. Powell: Allbutt's System, vol. vi., p. 48.) "*Face pallid.*" (R. Quain: Dictionary, p. 50.) "*Face suddenly becomes pale.*" (Bristowe's Medicine, p. 519.) "*Surface of body becomes pallid.*" (R. Quain: Dictionary, p. 50.)
(9) Coldness of skin.	"*Whole surface of body cold.*" (Ibid.) *Coldness of surface.*" (D. Powell: Allbutt's System, vol. vi., p. 48.) "*Suddenly becomes cold.*" (Bristowe's Medicine, p. 520.)
(10) Faintness.	"*Sense of faintness.*" (R. Quain: Dictionary, p. 51, 1882.)
(b) *Symptoms representing operations determining compensatory vaso-constriction in the somatic and thoracic regions.*	
(1) High tension of arterial wall.	"*Pulse small, hard, thready, and scarcely perceptible.*" (Allbutt's System, vol. vi., p. 50.) "*Diminution in size of pulse proceeding almost to extinction, a mere tightened thread being felt under fingers.*" (Ibid., p. 49.) "*Small pulse and of high tension.*" (Ibid., p. 34.)
(2) Splanchnic effect upon sweat glands.	"*Streaming with perspiration.*" (Ibid., p. 50.) "*Covered with sweat*" (R. Quain: Dictionary, p. 50.) "*Cold sweat.*" (Allbutt's System, vol. vi., p. 47.) "*Clammy sweat.*" (Bristowe's Medicine, p. 519.)
Further Points of Comparison.	
Painless type of simple gastro-circulatory attack.	*Painful type of gastro-circulatory attack (angina pectoris).*
(1) An attack is excited in the predisposed by oscillatory movements of the body occasioned by walking, running, swinging, or by a heaving movement as when aboard a boat at sea.	"Exercise induces an attack." (Bristowe, p. 519.) "On taking exercise premonitory symptoms are felt." (D. Powell: Allbutt's System, vol. vi., p. 48.
The attack is hastened by the presence of food, fluids, and flatus in the stomach, and probably results from the splashings of the contents against the gastric walls. A monotonous repetition of these impulses results in a summation of stimuli which ultimately induces activity of the implicated nerve centre.	"Flatulent distension of the stomach is frequently an exciting cause" of anginal attacks. (D. Powell: Allbutt's System, vol. vi., p. 29.) "Flatulent distension is a frequent concomitant of anginal paroxysms." (Ibid.)
This form of attack usually comes on after the patient has been under the influence of the movement for several minutes, and it undergoes abatement when the movement ceases.	"An oppressive meal of indigestible food brought on a first and distressing anginal attack followed by others." (R. Quain: Dictionary, p. 53, 1882.)

In some cases of gastro-circulatory attack in which irritability of the stomach or its nerve centres is a marked feature, a change of position from the horizontal to the vertical, rising from a chair walking across a room may precipitate an attack.	"In one of Stoke's patients the slightest muscular effort—that simply of moving his feet in bed—sufficed to precipitate an attack. The patient therefore went to bed wearing his clothes." (Whittaker: Twentieth Century of Medicine, vol. iv., p. 444.)
(2) Another variety of attack is excited by the presence of offending bodies in the stomach, often resulting from delays of digestion, the retention of undigested food, and the biochemical changes taking place in it.	"Dyspepsia is a frequent exciting cause of anginal attacks." (D. Powell: Allbutt's System, vol. vi., p. 29.)
The attack comes to an end after the expulsion of the offending bodies.	"The case may come to an end by expulsion of air from the chest." (Mackenzie: Diseases of the Heart, p. 47.) "Patient vomits and becomes easier." (D. Powell: Allbutt's System, vol. vi., p. 49.)
(3) An attack sometimes comes on as a result of sensory impressions or strong emotion.	"Emotional disturbance, fright, and pain will produce attacks." (Allbutt's System, vol. vi., p. 29.)
(4) The attack does not always come to an end upon the cessation of the impression which excited it. It is then probably caused by a chronic irritable condition of the nerve centres, or by the presence of a toxin in the blood stream.	
(5) The attack often comes to an end upon the administration of amyl nitrite, or nitro-glycerine.	"Amyl nitrite acted instantaneously." (Mackenzie: Diseases of the Heart, p. 50.)

Many of the symptoms referred to in the above schema, such as coldness of the skin, sweating, and pallor, when looked upon singly appear of little significance, but when seen as members of the orderly array of symptoms constituting the syndrome their importance is self-evident. They are then recognised as marks representing processes which move in obedience to economic purpose.

Thus, when we observe coldness of the skin, general pallor, shrinkage in the calibre of arteries and veins, and an almost empty pulse, we know that attenuation in the volume of the arterial stream traversing the vessels of the somatic region exists, and when we notice the presence of a feeble irregular, and intermitting pulse in conjunction with these symptoms we conclude that the volume of blood entering the heart is also small. Moreover, at the same time proof is not wanting of a dilated state of the vessels of the splanchnic region. A falling blood pressure observed at this stage of the seizure furnishes incontestable evidence of the existence of this condition, and the secretion of an abundance of pale urine retained during the course of the seizure but passed soon afterwards is confirmatory evidence of a strong order.

Consequently it may be inferred that symptoms occurring in the penultimate stages of the painful and painless types of the gastro-circulatory seizure, as scheduled under "Circulatory syndrome, Schema B," alike afford evidence of a circulatory crisis in being, in which the blood stream withdrawn from the coverings of the body, from the nerve centres in the medulla, and from the heart itself is massed in the splanchnic lacuna.

As all processes taking place in the animal organism are set into motion, controlled and directed in accordance with an economic purpose, so the gathering of the bulk of the blood volume in the splanchnic region and its displacement from accustomed channels observed in the gastro-circulatory attack is effected for a definite end. This purpose and the reasons thereof are referred to in the early paragraphs.

The resemblance existing between the painless and painful types of seizure observed in the schema renders it probable that they both belong to the same group, that the processes underlying the symptoms are directed from the same or associated centres, and in fact that the anginal attack is either a gastric reflex or springs from direct irritation of gastro-circulatory nerve centres.

The pain symptom in angina appears to be associated with spasmodic and patchy contraction of cardiac and arterial muscle occurring during the compensatory vaso-constrictor impulse and at a period when arterial blood is massed in the splanchnic region. This symptom I have treated at some length in a previous article.[8]

Streatham Hill, S.W.

[8] Practitioner, March, 1910.

FOUR CASES OF SPORADIC CRETINISM IN ONE FAMILY.

BY B. CROSSFIELD STEVENS, M.D. DURH., F.R.C.S. EDIN., D.P.H. OXON.,
ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOLS MEDICAL OFFICER, AYRSHIRE COUNTY COUNCIL.

THIS quaint little family with whom I have been brought in contact during school medical inspection is, I think, deserving of medical record for the following reasons:—(*a*) Sporadic cretinism is not common in this country; (*b*) four cases in one family is still more uncommon; and (*c*) four cases all with enlarged thyroid glands is rare.

Family history.—The parents of my cases are both strong, healthy, and temperate. The father is strong and his father was known to be a strong, healthy man. The father is of a sanguine and rather lethargic temperament; the children take after him in colouring of hair and eyes—the latter are somewhat almond-shaped and dull. The mother is a strong, healthy, hard-working housewife. She is the second wife and mother of all four children. The only child by the first wife is 19, tall and strong. Neither parent knows of any antecedents affected with swellings in the neck or stunted growth.

Locality.—There is nothing in the geology or water-supply of the district that could influence any goitrous tendencies, as is found where goitre is endemic. The children have not been imported from a goitrous district, and were all born in the same town.

Personal history.—There are three boys and one girl under consideration.

Name.	Sex.	Age.	Height.	Normal average height.
A. B.	M.	12 9/12 years.	3 ft. 9 in.	4 ft. 7 in.
B. B.	M.	11 ,,	3 ft. 7 in.	4 ft. 4½ in.
C. B.	M.	7 1/12 ,,	3 ft. 4 in.	3 ft. 11 in.
D. B.	F.	5 5/12 ,,	3 ft. 2 in.	3 ft. 4 in.

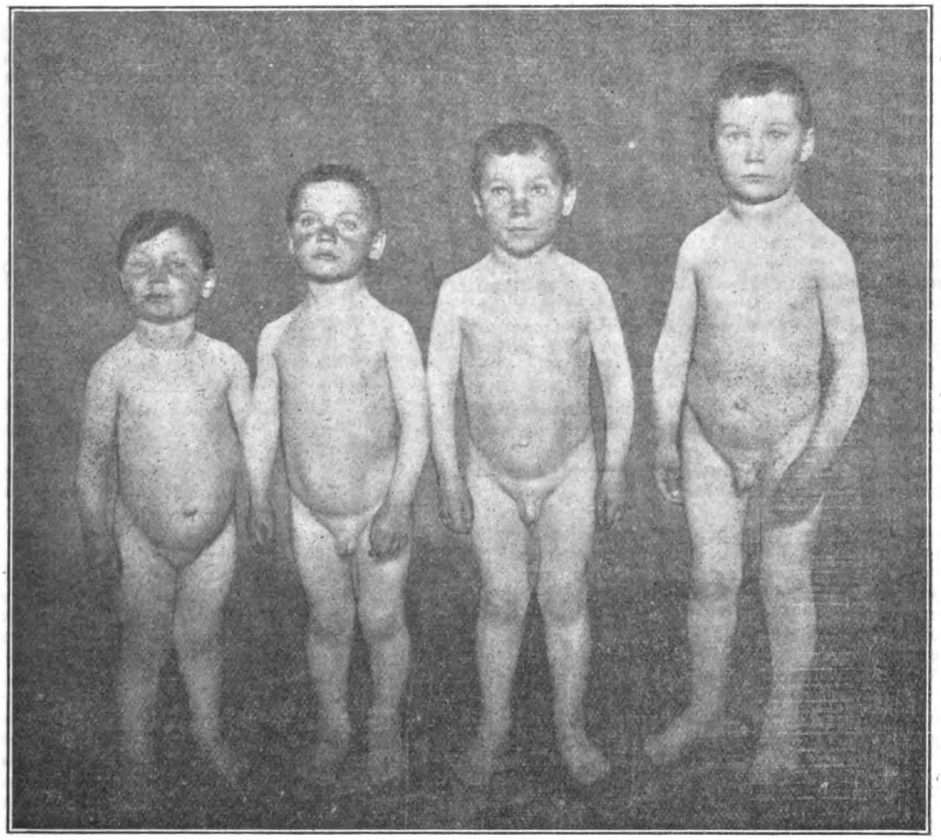
There is also a baby ten months old, who at present shows no signs of cretinism, though a colleague who saw the child some months ago asserts that it is becoming altered to a more Mongolian type of face. The mother says the child is very "nervy and jumpy." Two children were still-born. All the children were born with difficulty owing to their large size. This reason is given for the still-birth of the two mentioned above. The children all grew well until they turned three years, when growth became very slow, and about this time the swelling in the neck began to appear.

Symptoms: 1. *General.*—The three boys, as seen by the table given, are well under the average height. This does not apply so much to the girl, who has only lately stopped growing; she is 2 inches below the average height. The four are dull, placid, and inactive; they do not play and they dislike activity. They are, however, clean, affectionate, and polite. They have a fixed stolid expression, but can be easily amused or made to laugh. The mother says they weep on being slightly corrected or spoken sharply to. Their speech is somewhat hoarse, toneless, and short-sentenced. The sight and hearing are normal. The gait is slow and deliberate, but not markedly clumsy, though waddling and stiff. The patellæ are small and the feet are blue and clammy. The face has a myxœdematous look, the neck and shoulders are massive in three of them, and the hands are broad, stumpy, and cold. The nails are healthy. The anterior fontanelles are not patent. The eyes are rather wide set and have a somewhat Mongolian appearance in three of them. The nose is broad, thick, and freckled, and the mouth large. The teeth are fair. The hair is coarse and the scalp scurfy. The skin is somewhat rough and dry. The thyroid gland is enlarged in each case, though one lobe stands out more prominently than the rest of the gland. They each have strong-looking broad backs and buttocks, with a tendency to a protuberant abdomen and some lordosis. They were all late in walking. They all feel the cold very much, and generally huddle round the fire. The two eldest stand about the room like two old men, seldom speaking, and never wanting to go out for a walk or game.

A photo taken four or five years ago shows well the broad pug-nose and the thick lips of the three boys, who the mother said looked like niggers.

2. *Special.*—A. B. is nearly 13 years old and is 45 inches in height. He has had scarlet fever, measles, and whooping-cough. He has the coarsest hair and is perhaps the most typical cretin of the group, though he is not quite so lethargic as his second brother. Both testicles are present but undescended. He is 5 inches taller than the average child of five years.

B. B., the second boy, is 11 years old, is 43 inches in height, and weighs 4 stones. He has had measles, whooping-cough, and scarlet fever. He is very constipated and has gone a fortnight without an action of the bowels. He would as a baby lie for hours in his cradle without moving a muscle, and with his eyes fixed. He becomes blue and breathless on exertion, as is sometimes the case with cretins. He has one testicle in the scrotum; the other has not descended.



not without. Memory very weak; cannot learn poetry by heart. Very happy in school, seldom absent.

B. B. Always at bottom of class. Very much weaker in intelligence than A. B. Quite incapable of grasping what is taught him. Cannot work the simplest operations in arithmetic. Reading is very poor, but improving. Memory very weak, but can repeat little bits of poetry. Very happy in school, and seldom absent.

D. B. Came to school in September, 1909. Not incapable of learning, but very very slow. She knows most of her sounds; cannot distinguish "b" from "d" nor "q" from "p." No idea whatever of number. No control of her fingers; cannot write or draw. The essence of good nature and willingness. Perfectly happy at school.

C. B. Like D. B. in all respects, except that he writes well. Perfectly happy in school.

Remarks.—Cretin is derived by some from Creta = chalk, which explains itself, but not the etiology of the disease. One synonym (a loosely worded one) is infantile myxœdema;

A family of cretins.

C. B., the third boy, is nearly 8 years old, is 40 inches in height, and weighs 3½ stones. He is more intelligent and active than his brothers, and will go errands for his mother. He has the largest tongue and the least enlargement of the thyroid of the group. His teeth are worse than the others. He has some lordosis and a waddling gait, dragging and shuffling his feet. He has one testicle in the scrotum; the other cannot be felt. His tibiæ are somewhat curved.

D. B., the girl, is 5 years and 8 months old, is 38 inches in height, and weighs 3 stones. She has had pneumonia and scarlet fever. She is not so dull as her three brothers and walks rather better. She has the largest thyroid, also a protuberant abdomen and umbilicus. In proportion she has the heaviest-looking neck and shoulders.

Report of schoolmaster as to their mental and intellectual capabilities.—A. B. Always at tail end of class. Very attentive, but does not grasp what is taught him. Can work simple operations in arithmetic with help of paper but

this only applies to children up to 15 years. When symptoms of cretinism are present at birth they are due to an absence or arrest of development of the thyroid gland; but where cretinism appears during the first few years of life (as in my cases) it is evident that the gland has been fully formed at first, but that subsequently a degeneration, with atrophy of true gland tissue, has developed. My cases might be called cases of goitrous cretinism to distinguish them from cases of juvenile myxœdema; the latter term should only be applied where the thyroid is embryologically not developed or at most insufficiently so, and, after functioning for a while, atrophies. Rushton Parker[1] says that "cretinism due to goitrous degeneration of the thyroid seems to be disappearing from this country." This he attributes to improved sanitation and to the opening up of secluded valleys which he considers "are the worst breeding grounds of goitre and

[1] Brit. Med. Jour., August, 1896.

which are sufficiently secluded and benighted to induce frequent intermarriage among goitrous families."

It generally requires at least two generations to produce cretinism—goitre appearing in the first generation and cretinism only in the second or third. About 60 per cent. of cretins are females.

Sixty years ago goitre and cretinism were endemic in Somersetshire, as is described by Dr. Hugh Norris in the *Medical Times and Gazette* in 1848. In later years two new centres have been discovered—one in Khokand, Turkestan, and described by M. Guillaume Capus in his book "Les Médecins et la Médecine en Asie Centrale," the other by Dr. T. J. Tonkin in Gigata in Northern Nigeria, who estimated that 20 per cent. of the population had goitres. Jones, commenting on a case of goitre in mother and child, says in the *British Journal of Children's Diseases* that "it is not certain that there is any disease of the thyroid that is hereditary in the biological sense—i.e., is due to a transmissible innate variation; so that any part that heredity may possibly play must be an indirect one connected with perhaps the susceptibility to certain poisons." Leonard Williams (author of "Adenoids, Nocturnal Enuresis, and the Thyroid Gland"), in "Folia Therapeutica," says that "when there is reason to believe that the defect in the thyroid is congenital, it is nearly always to the mother, very seldom to the father, that the responsibility attaches." He also says that "many women who are thought to be sterile are only so because of the general failure to recognise the paramount importance of the thyroid gland in the function of reproduction."

Menstruation is practically absent in female cretins, but Wellesley Kendle showed a case before the Barnstaple division of the British Medical Association of a cretin, aged 9 years, who had menstruated from the age of 5 years and 2 months, in large amount, and every two to four months. After being put on thyroid extract the menstruation ceased. Byrom Bramwell reported a case of sporadic cretinism without amenorrhœa in THE LANCET. A patient, aged 36 years, whose height was 36 inches, with all the signs of cretinism, had menstruated regularly after the age of 25. Her intellectual development was that of a child of 5 or 6 years. During normal menstruation and pregnancy the thyroid gland enlarges; this opens up the large question of the relation between thyroid and ovarian secretions and cannot be discussed here.

Morbid anatomy and pathology.—There are three classes of thyroid inadequacy described—viz., (*a*) absence of thyroid gland; (*b*) atrophy of thyroid gland; and (*c*) with goitre. My four cases belong to the third class, and comparatively few sporadic cretins have goitre, in which respect they differ from endemic cretins, in whom goitre frequently occurs. Cretinism may develop in utero, but as a rule nothing is noticed until the third or fourth year, as in my cases. "The severity of the symptoms is proportional to the amount of destructive disease in the gland; the less the amount of secretion passing from the gland into the blood the greater the severity of the symptoms, just as in myxœdema in the adult."[2]

Differential diagnosis.—Mongolian idiocy has to be distinguished from cretinism, but the former is smiling and observant, while the latter is dull, apathetic, slow, and expressionless. Both may be treated by thyroid extract, but this treatment is disappointing in the case of Mongols. Achondroplasiacs may appear like cretins by the arrest of growth in their long bones, but this is noticed in infancy, whereas in cretins the disproportion between limbs and body only becomes evident later. Achondroplasiacs are not mentally deficient, and the skin and hair are natural, nor is there any apparent atrophy or hypertrophy of the thyroid gland.

Hill Abram has shown a case of the rare disease, cleidocranial dysostosis. The clavicles were absent, the cranium was brachicephalic, and the anterior fontanelle was open. The distorted vertex and the deficient development of the facial bones, the thick neck, short stature, waddling gait, undeveloped genitals, coarse hair, and broad hands, suggested some degree of athyroidism; on the other hand, however, the lad was intelligent, though emotional, and had no myxœdematous appearance.

Treatment.—My four cases have had practically no treatment. One boy was treated with thyroid gland in tablet form for a short time, but it was given in too large doses, and brought on nervous symptoms with trembling and tachycardia. I have advised the mother to go on with the tabloids she had, giving each child regularly a small dose once a day for from four to six weeks, then leave off for a week, and again proceed. Also, that the children should see a medical man at regular intervals. Diarrhœa is often a symptom of excessive dosage by thyroid extract.

In the treatment of cretins by thyroid gland one must bear in mind that owing to the rapid growth of a somewhat soft long bone deformities such as bow-legs may arise, and a scoliosis may become more marked unless care is taken to secure rest, massage, and properly controlled exercises. Treatment of marasmic children by thyroid gland is advocated by Leonard Williams and G. A. Sutherland. Speaking from an educational point of view, I think the ordinary day-school is the best place for cretins between the ages of 5 and 15 years, provided they are not slobbery, repulsive idiots, and provided that they are not exerted physically by drill nor mentally by lessons.

The accompanying photograph taken for me by my colleague—Dr. T. Lauder Thomson, the county bacteriologist—shows many features of interest, The goitres are apparent, also the short femora and rather curved tibiæ—the dark hands and feet due chiefly to the blue and cold condition, the broad, putty noses, and the peculiar eyes of the three youngest are noticeable. On measurement it will be found that the umbilicus is almost exactly midway between the soles of the feet and the crown of the head in each case.

County Buildings, Ayr.

[2] Murray: Disease of Thyroid Gland.

A NOTE ON THE TREATMENT OF THE PARTIALLY DROWNED.

BY J. A. BARNES, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON, S.S. "ALPHA," ROYAL NATIONAL MISSION TO DEEP-SEA FISHERMEN.

HAVING lately had to deal with a number of cases of drowning, I venture to put forward some conclusions I have arrived at, especially as regards their treatment. Apart from sequelæ, death from drowning appears to be due to (1) asphyxia from the mechanical action of the water entering and blocking the air passages; or (2) shock from sudden and prolonged immersion. These may be combined, but in most cases one or other is the prominent symptom. With regard to the first class of cases, if any considerable quantity of water has entered the bronchial tubes, unless it is very quickly expelled by a voluntary effort, I look upon such cases as hopeless. The condition is shown by the continued expulsion of froth when artificial respiration is performed, although the mouth and pharynx have been well wiped out before commencing.

It is the cases in Class 2, where shock is the prominent feature, to which I wish especially to call attention. This class includes most of the cases which there is any prospect of saving. In these cases there are usually unconsciousness, a feeble and intermittent pulse, intermission or complete stoppage of respiration, and, in fact, all the signs of severe shock. Often after the mouth and pharynx have once been cleared no more fluid or froth is extruded, the stoppage of respiration having acted, to a certain extent beneficially, in preventing the inspiration of fluid.

The usual directions given for the treatment of the apparently drowned are to perform artificial respiration and apply warmth. If, however, we look upon such cases as cases chiefly of shock, it is obvious that something more than this may be done. Shock may be looked upon as the result of a number of afferent impulses partially paralysing the vasomotor centre, and so causing a rapid fall in blood pressure; the result of this is that the greater portion of the blood of the body stagnates in the splanchnic area, and the brain, including the circulatory and respiratory centres, is robbed of its proper supply, and these centres are still further depressed. The result to be aimed at, therefore, is the driving of the blood from the abdomen, so that the brain may receive its proper supply. This I aim at by an attempt at auto-transfusion as follows. Having started an assistant on artificial respiration I firmly bandage the legs from the feet upwards. A roller towel is then passed round

the patient's abdomen, the two ends crossing in front. One assistant is told off to each of these ends. As the arms are brought down to the chest in the *expiratory* movement of artificial expiration (Silvester's method) these two assistants, grasping the towel-ends firmly with their right hands, pull them, at the same time making pressure on the abdomen with their left hands. In this way considerable squeezing of the abdomen is obtained. As the *inspiratory* movement commences the pressure is relaxed so as not to interfere with the expansion of the lungs. The process is continued synchronously with the movements of artificial respiration. My idea is that this acts beneficially in two ways: (1) it assists, by pressing up the diaphragm, to more completely empty the chest with expiration; and (2) it squeezes some of the excess of blood from the abdominal cavity. The bandaging of the legs and arrangement of the towel can be very quickly carried out with assistance, of which there is usually no lack in these cases.

Gravity should also be made to assist the flow of blood to the brain by keeping the head at a lower level than the body. I give a hypodermic injection of ether (30 minims) and usually one of strychnine as well. The objection to the use of these stimulants—that they stimulate an already tired centre and are quickly followed by increased depression—seems hardly to apply in cases of drowning, as when once reaction has set in recovery is usually rapid. Adrenalin chloride given hypodermically (30 minims of a 1 in 1000 solution) should act beneficially by raising the blood pressure. I have not yet tried it in a case of drowning, but intend to do so on the next suitable opportunity.

In conclusion, it should not be forgotten that the unconsciousness and other symptoms may be due to an injury sustained at the moment of falling into the water. As an instance I may mention a case I saw last winter in the North Sea. Owing to the capsising of his boat a man was thrown into the sea. As all the other boats and trawlers were to leeward of him and a strong sea was running, it was some time before a boat could reach him and pick him up. I could see the man on the water and noticed that he did not move or make any voluntary effort to save himself. When he was got aboard neither pulse nor respiration was perceptible. I at once commenced artificial respiration, but soon realised that the case was quite hopeless. It was then, when I came to examine him more thoroughly, that I noticed a wound in the parietal region with a well-marked depression of the bone. He had evidently been struck on the head by the boat as it overturned. It was, of course, out of the question to think of any operative treatment then, but the possibility of such an accident is to be kept in mind, as such a condition is otherwise not likely to be noticed in the hurry and confusion of attempting to resuscitate a patient.

DONATIONS AND BEQUESTS.—By the will of the late Mrs. Wilhelmina Bedford, who has left estate valued at £20,500, the residue of the estate with remainder as to one moiety is bequeathed to University College for the endowment of scholarships for the promotion of the study of zoology, and one moiety for the benefit of King's College, Cambridge.—Subject to a life interest, Miss Mary A. D. Harland has left £1000 to the Salford Royal Hospital.

SANITARY ASSURANCE ASSOCIATION.—The twenty-ninth annual meeting of the Sanitary Assurance Association, the offices of which are 7, Pall Mall, London, S.W., was held on June 10th, when the annual report was adopted, and Mr. Walter Butler, M.Inst.C.E., re-elected President. The annual report concluded with the statement that the advance made by science generally during the past half-century has been nowhere more thorough and manifest than in the domain of sanitation and hygiene, and claims that the association has been largely instrumental in raising the standard of sanitation to that which now prevails. At the time the association was founded hardly any standard was recognised, and the work which it did has certainly been productive of much good. The association intends to continue to enforce the fundamental principles which it was founded to maintain; and as the importance of sanitary efficiency in buildings of all sorts is now becoming generally recognised we can imagine that the work of the association will increase.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FACED RICE AS A DANGER TO HEALTH.

BY W. FOULKES LOWE, A.R.S.M., F.I.C.,
ANALYST FOR THE COUNTIES OF ANGLESEY, CARNARVON, DENBIGH, AND FLINT, AND THE CITY OF CHESTER;
AND
J. GEORGE TAYLOR, M.A., M.D. CANTAB., M.R.C.P. LOND.,
HONORARY PHYSICIAN, GENERAL INFIRMARY, CHESTER.

IN THE LANCET of Dec. 18th, 1909,[1] one of us described a case in which a pancreatic calculus of most unusual composition was discovered. The analysis of the calculus showed:—

Carbonate of lime	13·5 per cent.	Soluble.
Magnesia	Trace.	Soluble.
Silica	68·5 per cent.	Insoluble.
Alumina	18·0 ,,	Insoluble.
Ferric oxide	Trace.	Insoluble.
Magnesia	,,	Insoluble.

"There was no trace of phosphate in either the soluble or insoluble portion, and no oxalate. The sand appeared to form a nucleus for the carbonate of lime, and the grains appeared to be coated over with the carbonate." The presence of so large a quantity of silica and alumina was difficult of explanation.

More recently one of us has had samples of rice submitted for analysis. The rice samples were specially examined for mineral facing, as a practice has sprung up of facing rice with mineral matter, chiefly steatite, in order to improve its appearance, and no doubt also to enable inferior and damaged rice to be sold as the best. A full description of this practice is given in Dr. Hamill's report to the Local Government Board on the mineral facing of rice, but briefly it consists of treating the rice with oil, and then polishing it in drums with a mineral powder. It is carried on both in this country and abroad. In this way a mineral facing is left on the rice which is very difficult to detach, and practically the whole of it passes into the food when cooked.

The facing on the samples examined amounted to from 7 grains to 100 grains per pound of rice, and its composition consisted mostly of steatite, which is essentially a silicate of magnesium, but many samples were faced with a mineral consisting of silicate of alumina containing only a small quantity of magnesium. The facing removed from the rice was examined under the microscope, and in many cases was found to consist of sharp angular particles, very similar in appearance to broken glass. It seems probable that these samples were faced with ground mica and not steatite. Mica is more expensive than steatite, as it is used for insulation in electrical engineering, but the residues from electrical works might very well be employed for this purpose.

On May 11th, 1910, a case was heard in the magistrate's court at Flint in which the defendants were ordered to pay the costs of prosecution for selling rice faced with steatite. This particular sample of rice contained 86 grains of steatite per pound of rice. It is clear that it would not take long for a man to consume enough silica to form a nucleus for a calculus such as was found if he ate much rice. The patient from whom the pancreatic calculus was obtained had been in the habit of having a rice pudding for dinner every day for months, and he was the only member of his family who took rice so regularly. The patient himself consumed one pound of rice in from 8 to 10 days. We obtained two samples of rice from the shop where the man's rice was always bought. Only two qualities were stocked in this shop. One of these samples was pure unfaced rice containing less than 1 grain per pound of extraneous mineral matter; the other was a highly polished rice faced with steatite to the extent of 64 grains per pound. As the composition of the insoluble portion of the calculus is so similar to that of many of the

[1] J. G. Taylor: A Case of Syphilis of the Pancreas with a Pancreatic Calculus in the Duct, THE LANCET, Dec. 18th, 1909.

mineral facings found on rice it seems most probable that its origin was due to this facing. If this supposition is correct it seems that the adulteration of rice by facing converts a cheap and wholesome article of diet into a dangerous one. The Local Government Board has proposed a limit of 0·5 per cent., or 35 grains, per pound for mineral facing on rice, but as pure rice does not usually contain more than 1 or 2 grains per pound of extraneous mineral matter and the amount is frequently less than 1 grain it is difficult to see why so large a limit should be allowed, especially as there seems to be considerable danger in the practice.

CANCER WITH BONE METASTASES: CONDITION OF BLOOD.

BY GORDON R. WARD, M.R.C.S. ENG., L.R.C.P. LOND.

THE annotation in THE LANCET of June 4th entitled "Latent Cancer of the Stomach with Metastases in the Bone Marrow and Blood suggestive of Pernicious Anæmia" prompts me to send you a brief account of the following case.

The patient was a woman who had had rapid recurrence of an epithelioma after removal of the left breast for this disease. When seen she had a large mass over the sternum which gave rise to considerable pain, and there were small nodules in connexion with the second and third ribs on the left side. There was also a mass of enlarged glands in the right axilla, but no other metastases were obvious. The apparent involvement of the sternum and ribs suggested the probability of finding blood changes. A count showed: red blood corpuscles, 4,760,000 per c.mm.; hæmoglobin, 65 per cent. (Haldane-Gowers); colour index, 0·68. The normoblasts numbered 382 and the megaloblasts 104 per c.mm. All the nucleated cells were polychromatophile and some showed basophil granulation (Geimsa's stain). The white cells numbered 10,800 per c.mm. A differential count (500 counted) gave polymorphs, 61 per cent.; eosinophils, 0·6 per cent.; monomorphs, small, 31·2 per cent.; monomorphs, large, 4·8 per cent.; and myelocytes, 2·4 per cent. A post-mortem examination was not made on this patient, although she died shortly afterwards. The blood in a case of aneurysm pressing on and eroding the sternum was examined at the same time, but no nucleated red cells were seen.

Westminster Hospital, S.W.

THE INFECTIVITY OF SCARLET FEVER.

BY T. HUNTER, M.A., B.SC., M.D., CH.B. GLASG.,
MAJOR, I.M.S.; CIVIL SURGEON, MORADABAD, INDIA.

THE recent discussion in the columns of THE LANCET on the infectivity of scarlet fever induces me to publish a note on a case of this disease acquired in a remarkable manner.

The patient was a forest officer stationed in a particularly out-of-the-way part of the Sub-Himalayan Terai in India, and he had had no communication with the outer world for months except by letter. He developed a typical attack of scarlet fever. The diagnosis was communicated to him with the remark that it was a mystery how he had contrived to acquire the disease. The explanation of this mystery the patient himself was able to give. By the preceding week's mail he had received from Scotland a letter written by a young brother who had been sent home from school in England on account of an epidemic of scarlet fever in the school. The letter was written at home on notepaper embossed with the home address, so it was presumably notepaper which had not been at school, and the writer, as far as was known, had not had the disease and did not have it later. The case in India was an ordinary example of the disease.

THE annual prize giving at the London (Royal Free Hospital) School of Medicine for Women will take place on Thursday, June 23rd, at 3 P.M. Dr. H. A. Miers, F.R.S., Principal of the University of London, will present the prizes, and Mrs. Garrett-Anderson, M.D., president of the school, will be in the chair.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Cæsarean Section in the Treatment of Eclampsia Gravidarum.—Life History of Fibromyomata of the Uterus.

A MEETING of this section was held on May 26th, Dr. H. MACNAUGHTON-JONES, the President, being in the chair.

Dr. F. J. MCCANN read a paper on Cæsarean Section in the Treatment of Eclampsia Gravidarum. He said that opinions as to treating puerperal eclampsia may be divided into (1) those favouring expectant treatment, and (2) those favouring immediate and rapid delivery, although the majority of obstetricians in this country regard abdominal and vaginal Cæsarean section as being unjustifiable. Some time ago he saw a severe example of eclampsia gravidarum in a primipara aged 26 years. She missed her first period in September, 1907. On April 20th she was not feeling very well and had headache. Suddenly at 8 P.M., without any warning, she had two or three very bad fits. Dr. McCann found her semi-comatose, with livid face and swollen eyelids. The urine withdrawn by catheter was found to be solid with albumin. She had another severe fit. Her pulse was very rapid and her tongue had been badly bitten. It was at once decided to empty the uterus, but under deep anæsthesia the attempts at dilatation produced little effect. Severe fits were constantly recurring, and on more than one occasion she appeared to be dying. The Cæsarean operation was performed at 2.30 A.M.; the child when extracted was dead. After the operation she had only one fit at 8 A.M. Her condition gradually improved, and on April 30th the urine was found to be free from albumin. She is now in good health, but has not again become pregnant. Dr. McCann said that Cæsarean section for eclampsia had a high mortality because it was tried after all other methods had failed, and frequently when the patient's condition was hopeless. He suggested the following indications for this operation: (1) when the fits are severe and recur in rapid succession; (2) when labour has not commenced; (3) when the cervix is difficult to dilate from elongation, hypertrophy, or excessive rigidity; (4) when the mother is moribund and the fœtus living and viable; (5) when labour has commenced and there is found considerable disproportion between the size of the child and that of the pelvis; and (6) when the surroundings of the patient are suitable for a major surgical operation and when the services of an operator skilled in pelvic surgery can be obtained. Out of 28 cases of Cæsarean section the fits stopped completely in 14. Moreover, abdominal Cæsarean section, when rapidly performed, had less tendency to aggravate the fits than other methods of delivery. The author concluded by urging the necessity for a reconsideration of the desirability of rapid delivery in eclampsia, as the mortality from expectant methods of treatment is still about 20 to 25 per cent.—Dr. G. E. HERMAN said that he did not agree that the first indication of treatment was to empty the uterus. In a paper read before the Medical Society of London he had collected 2000 cases of eclampsia, and the comparison of the cases in which the uterus was rapidly emptied with those in which it was not interfered with showed that the fits were not stopped nor was the death-rate appreciably smaller. Dr. McCann had brought forward no evidence to alter this conclusion. The treatment of eclampsia by Cæsarean section had been adopted in many cases in many hospitals before 1902 and since, and the collected mortality was about 50 per cent. He believed that Dr. McCann was correct in putting the mortality of the disease treated by expectant methods at about 20 per cent. The conditions under which Cæsarean section had to be done in cases of eclampsia were as unfavourable as they could well be. He had read and heard many times of the cervix being undilatable; to his mind this only meant that the accoucheur would not give it time to dilate.—Dr. H. R. SPENCER did not think that it was in any way proved that delivery should be at once carried out, but he admitted that Bossi's good results obtained by the use of his dilator raised some doubts on this point. Abdominal section was very rarely indeed called for in eclampsia, for even if rapid

delivery was the right treatment the patient could generally be delivered by the use of Bossi's dilator or vaginal Cæsarean section (both of which methods, however, he regarded with some disfavour) in less time and with less danger than by abdominal Cæsarean section, which seriously endangered any subsequent delivery. Bossi's results gave a maternal mortality of only 9·45 per cent. (14 of 148 cases), and a fœtal mortality of 20·97 per cent., whereas with abdominal Cæsarean section the maternal mortality was six times as great (56·9 per cent.) and the fœtal mortality nearly twice as great (37·5 per cent.).—Dr. AMAND ROUTH said that Zweifel gives a mortality of 28·5 per cent. in cases under expectant, and 11·3 in those under active, treatment. If the patient be in labour relief can often be afforded by rupturing the membranes to relieve pressure, and delivering by forceps when the cervix is dilated. If in any given case rapid delivery is indicated and the cervix is undilated and rigid, he thought abdominal Cæsarean section, by which the child and placenta could be delivered in three minutes, was preferable to vaginal Cæsarean section or Bossi's mechanical dilatation of the cervix. He thought that Cæsarean section would be occasionally useful. He considered that Dr. McCann's indications were excellent, provided the cervix was rigid and undilated, and he thought any serious diminution in urea was another indication of value.—Mr. W. D. SPANTON said that some of the worst cases he had seen were post-partum ones. Abdominal Cæsarean section should be reserved for such exceptional cases as those in which the cervix was hard and undilatable or the pelvis contracted.—Dr. W. J. GOW said that in a case in which he had performed Cæsarean section for pelvic contraction there was a large amount of albumin in the urine, and several eclamptic convulsions occurred. In spite of this the patient made a good recovery. As to the high mortality alluded to, no doubt the patients died from the eclampsia and not from the operation. If the cervix was not taken up and was rigid and undilatable, Cæsarean section seemed to him the simplest and safest method to employ. Such a plan of treatment was, however, only indicated in very severe cases. In his opinion vaginal Cæsarean section was quite unsuitable unless the cervix was already taken up. He thought that emptying the uterus definitely increased the patient's chance of recovery if it could be done without inflicting serious injury upon her.—The PRESIDENT had some years since treated a case of eclampsia at the fourth month complicated with stenosis of the cervix, in which there was great difficulty in dilating the cervical canal. The patient was under chloroform for several hours, but death occurred before the uterus could be emptied. Under the old expectant treatment a certain number of patients always died. Some of the worst cases of eclampsia occurred post partum. Eight years ago he had published in THE LANCET an interesting case in which he had used Bossi's dilator. The uterus was myomatous and the urine contained a considerable amount of albumin; he succeeded in delivering with forceps, but the patient died shortly after delivery. He believed that there was a good deal in the old differentiation of the type of convulsions as denoting its severity—namely, the hysterical, the epileptiform, and the apoplectiform type. An anæmic albuminuric primipara with high blood pressure certainly presented a most dangerous form of eclampsia, and no doubt these patients were more liable to risks of septic invasion. He thought with Dr. Gow that there were circumstances in which Cæsarean section might be the only available method of treatment, when the only two courses open were to abandon the woman to her fate or to give her a chance by operative interference.

Dr. A. J. WALLACE read a paper entitled "A Contribution to the Life History of Fibromyomata of the Uterus." He related the history of ten cases observed over periods varying from 3¼ to 28 years. The first was that of a multipara who developed indications of valvular and mural disease of the heart. The pulse tension began to increase, severe headaches occurred and shortly after a rapidly growing fibroid was detected. Special treatment led to improvement of the cardiac condition and to lessening of the high pulse tension, and following on this double amelioration there occurred diminution in the size of the fibroid. This decrease was slow and gradual at first, but after it had been in progress for three years it occurred in jerks, as it were, each decrease being preceded by a febrile attack. Glycosuria appeared two years after the diminution of the tumour had begun, but it yielded to treatment. The blood pressure became further reduced and the headaches disappeared. In June the patient had a fibroid uterus "as big as the organ at the fourth month of pregnancy" (Dr. H. Spencer). In September of the same year Dr. Wallace found that the uterus was but slightly larger than the normal parous uterus and that it presented no signs of a fibroid. It was suggested that this case supported the conjecture advanced by Strassmann and Lehmann—that as with the new formations of thyroid tissue in Basedow's disease, so in certain cases of new formations of uterine tissues the changes in heart, uterus, and vessels are possibly to be regarded as symptoms of one disease. In the remaining 9 cases one was under observation for 20 years from the time when the impacted fibroid uterus was pushed up out of the pelvis until the fibroid disappeared entirely. In all of the remaining 8 cases shrinking of the tumours took place, in several to a very considerable extent. An analysis of the cases concluded the paper.—Dr. HERBERT SPENCER expressed his surprise that the tumour in Case 1, which when he examined it was as big as the pregnant uterus at the fourth month, should have completely disappeared in a few months.—Dr. AMAND ROUTH had seen uterine fibroids spontaneously disappear after the menopause, and mentioned an instance of this occurrence. This and cases quoted by Dr. Wallace only proved the desirability of radical operation when serious symptoms were developing, for his patient was a hopeless invalid for over 20 years and barely escaped with her life.—The PRESIDENT said that he was glad to hear Dr. Wallace's opinion that the histories of these cases were not to be taken as affording any argument against operation for myomata. They had now the details of some 8000 clinical histories which proved clearly that the dangers after from 40 to 50 years of age increased directly in proportion to the age.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on June 10th, Mr. A. PEARCE GOULD being in the chair.

Mr. R. C. ELMSLIE showed three cases of enlargement of the Tubercle of the Tibia (Schlatter's disease). The first patient was a boy who, about October, 1908, fell upon the left knee; from that time he had pain in the knee. In March, 1909, the tubercle of the left tibia was enlarged and tender. A radiogram showed the epiphysis of the tubercle apparently separate from that of the head. The swelling and occasional pain in the tubercle had persisted. The second patient was a boy who, on Feb. 10th, 1910, was kicked on the right tibia, in the region of the tubercle; there was no accident to the left side. At the beginning of March he felt pain in the region of the tubercle of the left tibia. Radiograms showed that the epiphysis of the tubercle was separate from that of the head on either side. The third patient was a girl who, in September, 1907, came to the hospital on account of pain and swelling in the knee, without a history of accident. In February, 1910, she returned to the hospital with both knees painful. The radiograms showed that the epiphysis of the tubercle on either side was continuous with that of the head, but there was an additional faint shadow, apparently of an additional epiphysial centre, lying in a superficial mass of cartilage. Mr. Elmslie also showed a case of Fracture of the Humerus at the site of an innocent cyst.—Mr. PEARCE GOULD described a similar case in which a useful arm was secured by making a free opening into what was at first diagnosed as a sarcoma.

Dr. H. D. ROLLESTON showed a case of Jaundice with Areas of Unpigmented Skin. The patient was a man, aged 59 years, who had had jaundice, which came on gradually, since December, 1909, and had progressively lost strength and weight. Over the thorax, abdomen, and back there were a number of elliptical or circular areas, usually about the size of a shilling, which were relatively unpigmented as compared with the remainder of the skin. In the centre of nearly all these areas there was a small cutaneous tumour, in some instances sessile and resembling a mole, in others pedunculated and somewhat resembling molluscum fibrosum.—Dr. F. PARKES WEBER suggested that these relatively unpigmented areas were spots of latent congenital leucodermia, being deficient in the normal pigmentation only, and that they had been brought into prominence by the general jaundiced hue of the skin.

Dr. F. J. POYNTON and Mr. WILFRED TROTTER showed a case of Cardiolysis. The patient was a male, aged 17 years, who was shown to the section 12 months ago. The object in showing the patient again was to add to the accurate knowledge of the after history of patients who had undergone that operation, for it was highly important not only to obtain a clear idea of the value of the operation as a surgical procedure, but also to place it in its correct perspective in the relation of the operation to the course of the disease for which it was undertaken. So far as the present case was concerned, it appeared that the operation had been in itself a successful one, but subsequent developments had shown that the health of the patient had deteriorated from other complications. Dr. Poynton and Mr. Trotter inclined to the view that the case was one of multiple serositis, probably of tuberculous origin, in which the relief of the embarrassed heart had done much to improve the patient's condition, but the disease itself had made decided advance in the respiratory tract.

Mr. J. P. LOCKHART MUMMERY described a case of Hyperplastic Tuberculosis of the Pelvic Colon.

Mr. CYRIL NITCH demonstrated a case of Congenital Hairy Mole.

Dr. WILFRED HARRIS demonstrated a case of Trigeminal Neuralgia of the Left First and Second Divisions treated by injections of alcohol.

Mr. S. A. CLARKE and Dr. A. F. HERTZ showed a case of Phlegmonous Gastritis, in which a cast of the stomach was vomited.

Dr. R. H. HODGSON showed a case of Pulmonary Phthisis with large Cavity, treated by inhalation of ether.

OPHTHALMOLOGICAL SOCIETY.

Optic Atrophy following Use of Arylarsonates in Syphilis.—Congenital Cataract.—Exhibition of Cases.

A MEETING of this society was held on June 9th, Dr. G. A. BERRY, the President, being in the chair.

Mr. ERNEST CLARKE read a paper on Optic Atrophy following the Use of Arylarsonates in the Treatment of Syphilis. The first case was that of a man, aged 46 years, who was given ten injections of 5 grains of soamin every alternate day, and after the last the sight became misty. Several months later he had three further injections of 5 grains. He had vision of barely hand movement in one eye and 6/12 with scarcely any field in the other. Both discs were atrophied. The next patient, aged 49 years, had 10 grains of orsudan on alternate days, and after the ninth injection the sight began to fail. Both discs became atrophied. He then stated what other writers had found after administration of the drugs atoxyl and soamin, and the number of cases in which optic atrophy had followed was considerable. The condition of the discs in these two patients left little doubt that the drugs were responsible. Possibly the combination of arsenic, aniline, and syphilis might be particularly destructive to the optic nerves, but the lesson he wished to point out was that great care should be exercised in the administration of arylarsonates; the eyes should be most thoroughly examined before and during the administration of the drug. That disease of the arteries, kidneys, or liver contra-indicated its use. That the dose should be carefully regulated according to the body weight and age of the patient, and it was doubtful if it ever was safe in anyone over 40 years of age. Colonel F. J. Lambkin, R.A.M.C., who is the great advocate of the treatment, had used it mostly, if not entirely, in young subjects. Mr. Clarke concluded by saying that when the profession had fully recognised the limitations of the use of the arylarsonates it might be that they would prove to be all that could be desired of them, but the question would arise as to the expediency of employing them at all for the treatment of syphilis. It was one thing to risk blindness in being treated for a fatal disease like sleeping sickness, and quite another to risk it in the treatment of syphilis, even if in some cases it were more successful than the ordinary and well-tried methods.—Mr. C. WRAY, in discussing the paper, pointed out the importance of giving the arylarsonates in accordance with the body-weight. Cases of blindness after their administration had been numerous, and it occurred in two sets of cases—after sleeping sickness and after syphilis; 15 per cent. of cases of syphilis recovered without the administration of mercury at all. Too little had been heard about the Wassermann reaction in treatment; it was used chiefly in diagnosis.—Mr. E. W. BREWERTON, the PRESIDENT, Mr. A. H. P. DAWNAY, Mr. R. W. DOYNE, Mr. E. TREACHER COLLINS, Mr. M. S. MAYOU, Dr. E. FARQUHAR BUZZARD, Mr. G. H. POOLEY, and Major MOLE took part in the discussion.

Mr. N. BISHOP HARMAN read a paper giving details of the Inheritance of Congenital Cataract in Nine Families. Of these five were of lamellar cataract, one of coralliform cataract, one of discoid cataract, one of form unknown, as the cataracts had been removed some years ago, and one of posterior polar cataract with microphthalmia. In the families with lamellar cataract several showed an inheritance through several generations and in numerous individuals. In one, a marriage of first-cousins seemed to accentuate it in their progeny. Another of these families showed grave mental disorder on both sides of several generations, several dying mad on the paternal side, and many suffering from epilepsy on the maternal side. The case of posterior polar cataract with microphthalmia was particularly distressing, for of five children born to an apparently healthy couple, of whom two were twin, the four surviving were all irremediably blind from the defective growth of the eye. It was noted that in several instances those affected with congenital cataract were mentally defective.

Mr. DOYNE showed some cases among members of his first family of "Family Choroiditis," and pointed out that the spots were exudations beginning in early adult life, but more generally later, increased very much in middle age, when, though the appearance of the lesion was gross, the sight was not proportionately affected, and, finally, in old age passed into atrophy with very great loss of sight.

Mr. C. S. BLAIR showed a case of Extensive Subconjunctival Rupture in a Buphthalmic Eye, with recovery; also brother of the above patient, also a subject of Buphthalmia, with complete congenital downward dislocation of lens.

Mr. DOYNE showed cases illustrating a form of Word-blindness, Guttate Iritis, also Test Lenses for the dark room.

Mr. A. H. THOMPSON showed a case of Vertical Nystagmus with movement so fine as to escape notice with the naked eye.

Mr. E. TREACHER COLLINS and Mr. A. C. HUDSON exhibited Microscopical Sections of an Eye with Unusual Yellow Patches in the Iris shown at the last meeting. The patches consisted of large polygonal cells with small shrunken nuclei and spongy cytoplasm, closely packed in a fine reticulum in which the degenerated chromatophores of the iris could be distinguished. The large cells were thought to be probably degenerated endothelial cells. A flat preparation of the choroid from the same eye showing very extensive colloid body formation was also shown.

Mr. ARNOLD LAWSON showed a case of Scirrhus of the Orbit.

Mr. W. LANG exhibited a case of Growth under the Conjunctiva.

Dr. RAYNER D. BATTEN showed a case of Raynaud's Disease and Mr. POOLEY a case of Traumatic Condition of the Retina.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Artificially Prepared Hypnotics.—Lupus Carcinoma.—The Cammidge Reaction.

A MEETING of this society was held on June 1st, Dr. CHARLES W. MACGILLIVRAY, Vice-President, being in the chair.

A discussion on the Artificially Prepared Hypnotics, their Use and Possible Abuse, was introduced by Dr. FRANCIS D. BOYD. He said that the mode of action of the synthetic hypnotics was a difficult problem. Meyer's hypothesis in explanation of the action of hypnotics was well known, and while it did not explain the action of some, it at least gave a working hypothesis. Briefly stated, the theory postulated that all chemically related indifferent substances which were soluble in fat and fat-like bodies must have a narcotic effect on living protoplasm. The action would be most prominent and powerful on those cells in whose chemical constitution the fat-like bodies predominated, particularly

if they were constituents of the functioning part of the cells. The narcotic tended to collect in the cells of the central nervous system, and so altered their physical condition and induced sleep. The strongest hypnotic possessed the greatest coefficient of solubility in fat. After alluding to the classification of hypnotics in reference to their chemical constitution he referred to types of mild hypnotics as amylene hydrate and chloralamide. The former, given in doses of ½ to 1 drachm, was not depressing, and he had observed no bad effects in cardiac cases. The latter acted well when given dissolved in alcohol, or better still in an acidulated alcohol, as in spiritus etheris nitrosi, though there might be a considerable latent period before its action commenced. The formamide present in this drug counteracted the depressing effect of the chloral. As types of medium strength, Dr. Boyd mentioned paraldehyde, sulphonal, and bromural. The first was one of the safest and most useful, and the disadvantage of its taste might be got over by giving it well diluted as an enema. In favourable cases sleep followed in 15 minutes. In doses of from 2 to 4 drachms per rectum it was a most useful hypnotic in pneumonia. In alcoholic subjects, however, its use was often followed by marked excitement. Sulphonal ought to be discarded because of its slowness of action, cumulative effects, and toxic properties. Bromural was especially useful in cases of emotional excitement. Of the more powerful hypnotics, chloral hydrate, veronal, and trional might be cited as examples. The first was now hardly ever employed, but veronal was very popular at present; it should never be given in the solid form or in milk, and large doses (15 grains) often produced unpleasant effects—e.g., rashes, fever, vertigo, &c. The prolonged use of veronal might induce various nervous phenomena. Trional was useful and induced a reasonably long sleep, but it was often slow in its action; its dose should not exceed 25 grains. A combination of amylene hydrate or paraldehyde with trional gave a rapid and more certain action. Hypnotics which should not be used because of their dangerous effects were isopral, chloralose, chloral-urethane, sulphonal, and tetronal. In cases of nervous excitement the best results might be obtained from a preparation containing bromide, as in bromural. In the insomnia from overwork or worry any of the milder hypnotics might be used, but frequent changes should be made and one hypnotic should not be employed continuously as tolerance was induced and the tendency to the formation of a drug habit was fostered. A hypnotic should never be given undissolved, because it might remain unabsorbed for a considerable period and induce sleep when not convenient. In each case the patient was a personal factor of considerable importance. It never could be determined when a patient might be peculiarly susceptible; universal erythema with pyrexia or vertigo might be produced by a single dose of veronal or chloral hydrate. The relief of pain by the employment of hypnotics might be regarded as an abuse on the part of the physician; in such cases even chloral hydrate induced no true sleep, but merely muscular quiescence. In the treatment of insomnia the physician should treat not the symptom but the diseased condition which induced the sleeplessness. Dr. Boyd advised all physicians who prescribed hypnotics to mark on the prescription "Not to be repeated." The sale of chloral hydrate and sulphonal was regulated by law, yet veronal and other dangerous hypnotics might be purchased freely. This was unsatisfactory. The Registrar-General's statistics afforded little information as to the prevalence of the drug habit. The association of the drug habit with alcoholism was alluded to, and Dr. Boyd asked whether it was desirable that further restrictions should be placed on the sale of hypnotics.—Dr. T. S. CLOUSTON said that the questions in relation to these drugs were: (1) Was there required a sleep producer, (2) or a general sedative, or (3) muscular relaxation? He had found that paraldehyde was most effective and least dangerous; he had known 2 ounces to have been administered by a nurse without harm to the patient. One had to keep in mind whether an instant or a gradual effect was desired. In nearly every case one obtained a better result by combining these drugs than by giving a single one—for example, a dose of sulphonal at 9 P.M. and one of veronal at 10 P.M. allowed a less dose of each to be given and a better effect resulted. He thought that bromide of potassium was neglected as an adjuvant to hypnotics and sedatives; thus 20 grains of bromide with a dose of paraldehyde gave a patient sleep and a quiet day following. He entirely differed from Dr. Boyd, who said that sulphonal was to be avoided. He had found 10 grains of sulphonal and 20 grains of bromide of potassium most useful in the excitement of old age. Veronal was an admirable drug when it agreed, but it often produced giddiness and erythema. A combination of veronal and trional in doses of 5 grains of each gave a better result than either singly—one obtained an absolutely certain effect. If a hypnotic were desired, then paraldehyde or veronal might be given; if a sedative, sulphonal or trional in combination with bromide. Hot milk administered with the drug prevented hæmatoporphyrinuria.—Dr. GEORGE M. ROBERTSON agreed as to the combination of drugs one of which acted promptly while the action of the other was prolonged. He was in the habit of giving 1 drachm of potassium bromide at 7 or 8 P.M., and when the action of this drug began about 10 P.M. a dose of paraldehyde was given when the patient was in bed. He knew a nurse who gave 2 ounces of paraldehyde to each of six patients; next day all were insensible as if under the influence of chloroform, but all recovered except one who was far advanced in phthisis. He said that 10 years ago sulphonal was universally praised by alienists, but owing to the number of deaths which resulted he had not employed this drug for the past nine years, and it was a drug specially dangerous to women; he had known of a death after three doses. Trional had been shown to be one of the most powerful agents in inducing degeneration of nerve cells.—Dr. J. O. AFFLECK said that hypnotics were more universally used now than ever before. Sleeplessness might be the main symptom, and he thought that this condition was less well borne now than previous to the introduction of hypnotics. Change of air or diet might cure the condition of sleeplessness and thus the use of hypnotics might be avoided. He had found a combination of bromides with tincture of hops often of great value in simple insomnia. The same hypnotic might be of use at one time and quite fail at another in the same patient. He had known of one case of the drug habit with paraldehyde. Chloral was valuable in reducing the delirium of advanced typhoid fever (coma vigil), and also in the delirium of pneumonia. He had not experienced untoward effects with trional or sulphonal, but he had seen disquieting results from veronal. All such drugs had to be carefully watched, as some were cumulative and others were depressing.—Dr. W. C. SILLAR said that the question of combination was, perhaps, the most important factor in the discussion. A purgative pill was almost invariably compound, so that small doses of each drug might be employed, and for the same reason a combination of hypnotics gave greater certainty with small doses of each. The great desire was to obtain a rapid effect, and therefore the question of solubility and absorbability had to be considered. On account of these properties alcohol was one of the most useful of hypnotics, and a glass of beer or stout at bed-time might well replace the tincture of hop which had been recommended. If a hypnotic were prescribed along with a diaphoretic probably a much more profound action would be obtained. The chemical constitution of paraldehyde resembled that of an alcohol, and this might account for its useful action as a hypnotic.—Dr. JAMES RITCHIE said that an opiate afforded the best relief for pain, while if the excitement were due to overwork bromide was most satisfactory. If the latter condition was associated with exhaustion, then a stimulant in the form of sal volatile should be added. In the aged or debilitated soup was a good form of stimulant, and in young people a large dose of Mindererus's spirit to dilate the capillaries was efficacious. He had not used sulphonal for many years because of the ataxia which it produced.—Dr. MACGILLIVRAY, Dr. R. A. LUNDIE, and Dr. GEORGE HUNTER took part in the discussion, and Dr. BOYD replied.

Dr. NORMAN WALKER read a paper on the Treatment of Lupus Carcinoma. He spoke of the increased frequency of this disease within recent years and of the gravity of the prognosis in such cases. He narrated the history of several cases treated by X rays and excision some years ago, with the result that many of them died. He was so disappointed with this form of treatment that during the past few years he had been in the habit of scraping the surface thoroughly; and having waited until all bleeding had ceased, using it might be, adrenalin, he then cauterised the raw surface with arsenious acid, caustic potash, or chromic acid. If the lupus carcinoma were extensive the patient might require to be anæsthetised, otherwise a local anæsthetic was alone

required. In every case of lupus in old people there was grave risk of it becoming carcinomatous. Formerly Dr. Walker advocated excision, but not now, as he thought that the disease, being very superficial and having a layer of dense connective tissue beneath it, scraping was the better plan. He had had uniformly bad results with excision, but uniformly good results with scraping, and the scar was as good as could be expected.—Dr. W. ALLAN JAMIESON said that cancer was apt to develop in cases of extensive lupus, and especially if it were on exposed parts. Exposure to the weather might induce cancer as well as X rays. Tension of the part had a good deal to do with the production of carcinoma lupus as the opening and shutting of the jaws. X rays were a frequent cause of this degeneration because they produced telangiectases, and by the irritation of these cancer was induced. Long ago Mr. (now Sir) Jonathan Hutchinson had said that excision was of no use in this disease. By the use of arsenious or chromic acid tissue was not removed, and this did not increase tension and was a great improvement in the treatment. In one situation of lupus, that of the nose, X rays had given brilliant results and scraping had here been of no use.—Dr. R. CRANSTON LOW also spoke.

Dr. WILLIAM RUSSELL read a communication on the Cammidge Reaction in Abdominal Disease. In view of the importance of accurate differential diagnosis in diseases of the abdomen any new aid must be carefully examined. With this object Dr. Russell for the second time took up the examination of the urine by Cammidge's method. The claim of the author of this test was that, with certain reservations, the reaction was indicative of the existence of pancreatitis—a disease common and serious, it was alleged, but which hitherto had escaped notice, but was now recognised as such for the first time by this product in the urine. The Cammidge reaction claimed to be a pancreatic reaction, and if this were not the claim then the performance of the test could at best be merely the demonstration of a chemical vagary in the individual, while if the claim were abandoned and at the same time the value of the reaction be asserted, they got into a region somewhat outside either the pale of scientific medicine or of logical thinking. The reaction could not both be and not be a sign of pancreatitis. The liver was a great excretory gland through its biliary function, it was indirectly the same in virtue of the chemical synthesis effected by its cells in the formation of urea, and it protected the body from the action of various toxins; through its glycogenic function it stored up energy. The influence of the bile in digestion was relatively insignificant. The pancreas, on the other hand, was a great secretory gland and performed no such functions as the liver; it was comparable to the salivary glands; its disturbances affected the value of its secretion. Injury to the liver by way of the blood or lymph was common. In the pancreas acute necrotic and hæmorrhagic inflammation was known as a highly mortal malady, but it had not been shown that these conditions arose from direct infection, while the cirrhosis of this organ had no clinical significance apart from the production of diabetes in some instances. Any absorption from the gland must be from its own secretion or of an altered enzyme, and the latter were protein bodies, not carbohydrate bodies, and presumably could not therefore be the source of the substance in question. The clinical pathology of the two glands was thus fundamentally different, and care had to be taken that clinical contentions regarding the pancreas were not based upon an imaginary pathology of the organ. In the present investigation the urine of patients suffering from abdominal symptoms or definite abdominal lesions was examined with the object of ascertaining whether any assistance was to be obtained from the presence or absence of the reaction in making a differential diagnosis. Tables were given of 78 types of abdominal disease. One case of necrotic pancreatitis gave a prompt and marked reaction. Another positive reaction was obtained from a man with indefinite gastric symptoms with toxic asthenia. The occurrence of melæna, however, in this case argued against a diagnosis of pancreatitis; at the necropsy a sloughing malignant growth was found in the stomach with secondary growths and necrotic areas in the liver, while the pancreas seemed normal. If disturbance of liver function could give a marked Cammidge reaction, there ceased to be any reasonableness in associating the urinary finding with pancreatic disease. Three cases of cirrhotic liver gave positive reactions. The ascitic fluid in two of these gave the reaction; while two cases of catarrhal jaundice were positive, and in seven cases of gallstone colic six observations were positive and three negative. Of 55 cases of gastro-intestinal derangement or of actual abdominal lesion the Cammidge reaction was negative in 26, while 29 cases gave a positive reaction. In spite of Dr. Russell's earnest attempt to find some value in the test, he entirely failed to obtain any indication from it of the existence of pancreatic inflammation or even any sure light and guidance as to the state of pancreatic secretion or of pancreatic digestion. Five check cases were taken with no abdominal symptoms; one was a case of arterio-sclerosis with normal pancreas, which gave a negative reaction once and on three occasions a positive reaction; a patient suffering from subacute rheumatism gave a positive reaction on three occasions. Seven observations made on three of the staff gave six positive reactions and one negative. From these results it was seen that a positive Cammidge reaction might be obtained from the urine of persons in good health, as also from persons suffering from a great variety of abdominal disorders or other diseased conditions; it might be present when the necropsy showed that the pancreas was apparently healthy. These definitely excluded pancreatitis as the cause of the Cammidge reaction. That the reaction was a reliable guide to the condition of the pancreas had not been borne out by Dr. Russell's observations, and indeed they seemed to negative such a contention. Even putting pancreatitis out of account, it might still be contended that the substance found in the urine was absorbed from the pancreas; but the pancreatic enzymes are proteid substances, while the substance in question is a carbohydrate. But even were such absorption the source of the substance they would require to recognise that the absorption took place in so many different conditions, was so variable in amount, and so apparently erratic in the times of its appearance that its presence as an aid to abdominal diagnosis was entirely negligible, and if depended on might be wholly misleading. The substance was probably a pentose, and its composition did not *a priori* suggest the pancreas as its source, but led rather to the consideration of intestinal processes and of the hepatic functions. In these regions it seemed to Dr. Russell that they were on sounder ground when seeking a source for this new urinary constituent. German, French, and American observers have noted that the reaction was obtained in diseases other than pancreatitis, and others have found it absent in pronounced cases of that disease. Cammidge's reaction was one of a number of urine reactions which might accompany alimentary error; to claim for it any higher position in diagnosis or prognosis was not warranted, and practically tested, as Dr. Russell had done, it signally failed.—Dr. D. CHALMERS WATSON pointed out that the interesting results which Dr. Russell had recorded were practically identical with those which he had described for a much larger series of cases two or three years ago. He differed, however, from Dr. Russell in the interpretation of the results, as he was satisfied that the pancreatic reaction test was of great value in diagnosis and a useful guide in treatment. Dr. Russell had approached this test from the standpoint of its being *pathognomonic of pancreatitis*. He (Dr. Watson) doubted if anyone definitely made that claim. In any case he did not, but he regarded the presence of a marked pancreatic reaction as an indication of a functional derangement of the pancreas of an important character, and one which was in the main amenable to dietetic treatment. Therein lay the special value of the test. Attention was drawn to the existence of clinical cases, variously diagnosed as indigestion, gout, and the like, which were associated with a marked pancreatic reaction in the urine, where the symptoms improved or disappeared coincidently with the disappearance of the pancreatic reaction in the urine under the influence of appropriate diet. The test had, in Dr. Watson's view, to be looked at from a much wider standpoint than had been indicated in Dr. Russell's interesting paper.—Dr. RUSSELL replied.

EDINBURGH OBSTETRICAL SOCIETY.

Treatment of Vomiting following Chloroform Anæsthesia.—Practical Points in the Life-history of Uterine Fibromyomata.—Pelvic Abscess.

A MEETING of this society was held on June 8th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Dr. J. W. KEAY read a short note on the Treatment of

Vomiting following Chloroform Anæsthesia, including the use of adrenalin. Slight sickness after chloroform anæsthesia is very common and leads to no actual danger; occasionally, however, by its persistence the patient's condition is rendered grave, and effectual means are eagerly sought for. In slight cases in nervous patients an enema of bromide and chloral will suffice to stop the sickness. In ordinary cases no foodstuff should be given by the mouth. Thirst can be assuaged by saline enemata or by rinsing out the mouth with aerated soda-water or hot or cold lemon-water. Where the anæsthesia has been prolonged and probably some chloroform been swallowed with the saliva the stomach is much relieved by copious draughts of hot water with bicarbonate of sodium, along with counter-irritation to the epigastrium. The serious cases of chloroform sickness are prone to occur after major gynæcological operations attended with some degree of shock. The disturbing condition of distension of the intestines is present and may be associated with intestinal paresis. In such cases the vomit is often not only bile-stained, but is coffee-ground from the admixture of blood. Sometimes the vomiting does not begin in these cases till from 12 to 24 hours after the operation. But with the persistence of the vomiting the pulse becomes rapid, and the case may end fatally in three or four days. Besides giving saline draughts by the mouth, saline enemata, and a purge, Dr. Keay recommends the use of solution of adrenalin chloride (1 in 1000) in 5-minim doses, if necessary every two hours. He believes it acts by blanching the vessels of the stomach and so preventing the bleeding which produces the black vomit. It also stimulates the peristalsis of the stomach and intestine, relieving the distension, and acts as a stimulant to the heart.—Dr. J. HAIG FERGUSON, Dr. J. LAMOND LACKIE, and the PRESIDENT discussed the paper and Dr. KEAY replied.

The PRESIDENT read a paper on Some Practical Points in the Life-history of Uterine Fibromyomata. The etiology of uterine fibromyomata remains a profound mystery; whether they are developmental or acquired has yet to be proved. They practically never manifest themselves before puberty and seldom commence of themselves to give evidence of their presence after the menopause. From this it would suggest itself that there may be much in ovarian influence, and the frequency of cystic ovarian conditions complicating their presence is undoubted. They seem to occur with practically equal frequency in married and single, but a considerable amount of controversy still exists as regards their relation to pregnancy. From over 400 cases where the President had performed hysterectomy or myomectomy there were 39 per cent. single and 61 per cent. married. Of the married, 42 per cent. were childless; 40 per cent. of those who had children had only one child, while the average number was 2·6. The average age of the last child before the operation was eight years (no widows were included). One can infer, therefore, that the mere occurrence of marriage has little or nothing to do with their presence, but so far as child-bearing is concerned, fertility is much impaired. These tumours have a distinctly sterilising effect; and probably pregnancy has a distinct stimulating effect upon their growth. During pregnancy they increase in size and remain larger after its completion. From this enlargement they commence to develop symptoms, one of the chief being sterility, either absolute or indirect, due to the frequency of abortions. Fibroids and pregnancy are fraught with much danger; women with fibroids sufficiently prominent to direct attention to their presence are safer single, and if married, safer sterile. One of the main characteristics of fibromyomata is the frequency with which they undergo degenerative change, 34 per cent. of his cases showing this occurrence. One would expect this from their tendency to develop an excess of fibrous tissue and from their having poor and difficult circulation. Cystic formations following degenerations are common. Malignant or sarcomatous change is extremely rare; it was only met with twice in his 425 cases. This is not in accord with other observers. The disparity is probably due to the fact that microscopic evidence alone is taken as decisive; whereas many cases, which clinically cannot be said to be malignant, have numerous embryonic connective-tissue cells which simulate sarcomatous tissue. Round the bed of the tumour veins are numerous and phlebitis is not uncommon, spreading from them to the lower limbs; he has met 14 cases of an aggravated form, in 9 of which both legs were affected. These lead to prolonged invalidism for months, but he (the President) now operates at once, and though there may be a short temporary increase of symptoms yet the condition rapidly diminishes. Fibromyomata delay the menopause, and it is at this time that they are specially liable to develop degenerative changes. Sometimes the delay of the menopause is extreme. One of his patients was 61 years, and yet with no cessation of menses, and other five were over 56 years when operated on. In 13 cases out of 425 he operated after the menopause for various conditions, as a calcified tumour causing pressure symptoms, sarcoma of tumour or uterine mucosa, twisted uterus, fibrocystic degeneration causing increase of growth, &c. After the menopause the tendency is towards atrophy and quiescence of the tumour. Post-mortem statistics show that 1 woman in 5 has fibroid nodules in the uterus, but in a very small proportion do they grow to any dimensions or assume characters of a morbid type giving rise to symptoms. They may be considered as harmless growths which only demand attention when they give rise to symptoms. Some consider that they should be removed whenever recognised in all circumstances. The speaker is entirely at variance with this view, as only a small proportion of fibroids give rise to symptoms and there is plenty of time to arrange to treat them if required. Malignancy is an exception and sudden dangers are very rare. But when symptoms develop, he strongly supports their removal. To wait on the menopause is too indefinite and even then does not ensure safety. The risk of operation is now so small that it is folly to undergo years of invalidism for a problematical healthy old age. A 2 per cent. mortality risk is worth running when benefit is to be attained, but not on a chance of avoiding probable trouble.—Dr. J. W. BALLANTYNE, Dr. HAIG FERGUSON, Dr. W. FORDYCE, Dr. E. W. SCOTT CARMICHAEL, and Dr. LAMOND LACKIE discussed the paper, and the PRESIDENT replied.

Dr. LAMOND LACKIE read notes on two unusual cases of Pelvic Abscess. Both were primarily cases of right-sided puerperal parametritis which went on to pus formation. In the first, the pus burrowed backwards along the posterior part of the iliac fossa, passed through the lumbar aponeurosis, and then turning forward appeared in the triangle of Petit. In the second, the area of abscess formation was surprisingly limited, for the inflammatory process had been going on for months. The patient suffered very acute pain in the region of the greater sciatic notch. No fluctuation could be made out per vaginam, but there was distinct œdema of the skin on the buttock. On cutting down towards the notch a small quantity of pus escaped, and on passing forceps through the sciatic notch about half an ounce of pus welled out. Both patients rapidly recovered after evacuation of the pus.—Dr. FORDYCE, Dr. SCOTT CARMICHAEL, and the PRESIDENT made remarks on the subject.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Goldscheider has been appointed to the charge of the Medical Polyclinic to succeed Professor Senator, who is retiring.—*Breslau:* Dr. R. Scheller, *privat-docent* of Hygiene, has been granted the title of Professor.—*Freiburg:* Dr. Otto Pankow, *privat-docent* of Midwifery and Gynæcology, Dr. Oswald Bumke, *privat-docent* of Psychiatry, Dr. Edgar Gierke, *privat-docent* of Pathology and Anatomy, and Dr. Hermann Schridde, *privat-docent* of General Pathology and Pathological Anatomy, have been granted the title of Extraordinary Professor.—*Kiel:* Dr. Louis Michaud of Berne has been recognised as *privat-docent* of Medicine.—*Lille:* Dr. Oui has been appointed to the chair of Clinical Midwifery in succession to Dr. Gaulard.—*Lyons:* Dr. Roque has been appointed to the chair of Clinical Medicine in succession to Dr. R. Lépine.—*Marseilles:* Dr. Guérin-Valmale of Montpellier has been appointed to the chair of Clinical Midwifery in succession to the late Dr. Queirel.—*St. Petersburg Military Medical Academy:* Dr. A. P. Tavitski has been appointed Professor of Medicine and Dr. G. P. Féderoff Professor of Surgery. Dr. P. S. Ikonnikoff has been recognised as *privat-docent* of Surgery.—*Stockholm:* Dr. J. A. Dalén, Professor in the Lund Faculty of Medicine, has been appointed to the chair of Ophthalmology in succession to the late Professor E. J. Widmark.—*Strasburg:* Dr. von Lichtenberg has been recognised as *privat-docent* of Surgery.—*Tomsk:* Dr. A. N. Bogoratz has been recognised as *privat-docent* in Surgery.

Reviews and Notices of Books.

Royal Commission on the Poor-laws and Relief of Distress. A course of Nine Lectures delivered on the Report of the above-named Commission in Sheffield during the Winter of 1909–1910. With a Preface by Dr. H. SCURFIELD, Medical Officer of Health for Sheffield, one of the Honorary Secretaries to the Committee which promoted the course. Sheffield: Sir W. C. Leng and Co. (*Sheffield Telegraph*), Limited. 1910. Pp. 56. Price 4*d*.

THE literature of Poor-law reform is assuming great dimensions, but the pamphlet in which the *Sheffield Telegraph* has reissued nine lectures on the subject delivered in that town contains useful contributions to a discussion which seems likely to be prolonged considerably before any statutory innovation of importance takes place. The citizens of Sheffield have had the advantage of hearing from their own lips the views of two of the Minority, and if Mrs. Sidney Webb and the Dean of Norwich have not added greatly to that which was already known of their opinions and their arguments, they must have enabled those who listened to them to grasp the principles upon which the Minority recommendations are based, as a prelude to judging of the practicability of the policy to which its champions declare adherence. Mrs. Sidney Webb accordingly figures in the reprint before us as the whole-hearted champion of a system having for its proposed object the prevention of destitution, and she urges all to seek this Utopian goal, with more success than she meets the arguments of those who decline to efface from their minds their knowledge and experience of Poor-law relief as now administered, of its difficulties and its successes. Dr. Russell Wakefield dwells upon the question of the treatment of the able-bodied as raised by the two Reports, the point of divergence at which, we believe, he finally determined to sever himself from the Majority, headed by Lord George Hamilton, and to append his signature to the Report of the Minority.

Other Commissioners, from the side of the Majority, who have lectured at Sheffield are the Rev. L. R. Phelps and Mr. F. H. Bentham, and with these are associated in the same course Dr. J. C. McVail and Miss Marion Phillips, members of the medical profession employed as investigators on behalf of the Commission, Mr. R. H. Tawney, also so employed, and Mr. Bernard Bosanquet, whose wife was a Commissioner. The paper read by Mr. H. J. Manton, who was not connected with the Commission, represents the case of the guardians, a body much abused and threatened with speedy extinction, but like other threatened institutions possibly destined to enjoy prolonged, if reformed, existence.

If we say that Mr. Manton's contribution to the volume is the most valuable that it contains, we do so from no desire to disparage the others, particularly those which follow it, but because it puts the side of which least has been heard in a many-sided discussion with clearness and force. Mr. Manton has had considerable practical experience of Poor-law work. He has been chairman of the Birmingham board of guardians and vice-president of the Poor-law Unions' Association, he avows himself a member of the progressive school of guardians, and he combats alike the views of Mrs. Sidney Webb on guardians, the proposals of herself and her colleagues for their abolition, and the Majority's advocacy of selected committees. Mr. Manton, in fact, takes his stand by the *ad hoc* elective authority, and he defends it with considerable force and cogency, both as to what it has done in the past and as to what it should achieve in the future, if given a fair field for its efforts. The soundness of many of his arguments comes near to establishing his case; but Mr. Bentham, ex-president of the Bradford board of guardians and a member of the Commission, follows him and brings the matter back to that perplexing point at which reasonable argument is found weighed in the balance against undeniable fact. The direct election by the ratepayer of his representatives, who shall be the best qualified of those offering themselves for the purpose, has all in its favour which is independent of past experience. In fact, however, it seems to be beyond dispute that very many who might do good service, perhaps the best, in administering public assistance do not, and will not, face public election, and two-thirds of the electorate care so little that they never vote. Mr. Bentham questions in these circumstances "whether it is really a denial of the democratic principle to suggest that a popularly elected body should be allowed to select its best citizens to administer a particular branch of public service," and as long as the best citizens will not brave the disagreeable features of an election, and are liable if they do so to be beaten by those less worthy, there is much in favour of some such form of selection as the Majority Report has suggested. The questions raised by Mrs. Sidney Webb, the reply of Mr. Manton, and the further comment furnished by Mr. Bentham in themselves render the Sheffield lectures worth reading.

For medical men Dr. McVail's contribution to the series will be found to be a readable epitome of his opinions and suggestions already made public in an ample and more exhaustive form, and the points which he raises should not only be considered by members of the medical profession whether engaged in Poor-law medical work or independent of it, but also by the lay public, in whose interest he puts them forward. Dr. McVail, among other matters, reiterates in particular his desire that in the carrying out of any scheme of extended medical provident institutions "every doctor on the institution list should make a periodical, though not necessarily a frequent, inspection of all members under his charge." This may be a counsel of perfection for the realisation of which we shall have to wait long, but its ventilation among those likely to be affected by it as members of such institutions, and much else that Dr. McVail has to tell them, should impress upon them the advisability of early attention to ailments which may appear to them to be trifling. He devotes a passage in the earlier portion of his paper to "delay in seeking medical advice," and the effect of such delay through prolonged illness, permanent incapacity, and death of the bread-winner, in producing pauperism.

We are glad to note that Dr. Harold Scurfield in his brief preface records that the lectures excited a great deal of interest in Sheffield. This subject, of such momentous interest to all classes of the community, is unfortunately one which cannot adequately be considered without study of its details, and, as Dr. Scurfield explains, "few persons will wade through the bulky volumes of the Commissioners' report, and consequently many remain in ignorance of the far-reaching nature of the issues dealt with."

Die Krankheiten der Nase und des Nasenrachens, mit besonderer Berücksichtigung der rhinologischen Propädeutik. (*Diseases of the Nose and Naso-pharynx, with particular reference to Rhinological Method.*) By Dr. CARL ZARNIKO. Third edition. With 166 illustrations. Berlin: S. Karger. 1910. Price, paper, 18 marks; bound, 19.60 marks.

TO call Zarniko's well-known work upon the nose and naso-pharynx unique would scarcely amount to an exaggeration, for we know of no other in which is contained in so complete and all-embracing a fashion the kind of material that is herein presented. In many respects, no doubt—in the arrangement and subject-matter of many of the chapters, for example—the book is in no way superior to half a dozen other standard works on rhinology; but in respect of its combination of comprehensiveness, lucidity, and balance

Zarniko's treatise stands first, even though it will be our duty to point out several gaps.

It is with what is termed in the original the *Propädeutik* (a word that can best be rendered in English by the old-fashioned *Institutes*) of rhinology that the author chiefly concerns himself—with the anatomy, that is to say, physiology, pathology, and methods of diagnosis and treatment. And although this entails a handling of the subject in the manner of the pure scientist, he nevertheless so vitalises the dry facts with the practical spirit of the clinician that there is an entire absence from his work of the musty atmosphere of the museum and the bone-room. Each item falls into place according to its clinical and not according to its academic importance.

In the section devoted to physiology the author has gathered together nearly all the theories that have been produced to explain the functions of the various structures in the nose and throat, and we are filled with admiration at the fair and unbiassed hearing he grants to each in its turn. The physiology of olfaction is particularly fully described. We confess we should have liked to hear the author's views upon the researches of A. Most and Z. von Lénárt on the functions of the tonsils, which seem to show that they are lymphatic glands to which the nasal lymphatic circulation tends, a theory which certainly clears up some, at least, of the mystery surrounding the physiology of these bodies. The author's presentation of the different opinions that are held regarding the functions of the nasal accessory sinuses also includes almost everything that has been said and written on the subject. At the same time we miss the theory that the sinuses are merely passive cavities, whose only function, if we may call it a function, is to render the facial skeleton at once extensive, protective, and light.

As in the other sections, so in those dealing with pathology and treatment, the predominant features of the work are exhaustiveness, moderation, and sanity, although we may here and there come across a pronouncement which engenders some doubt in the reader's mind. There are not many specialists, we imagine, who would place so much reliance on transillumination of the frontal sinus as the author does. And, in like manner, we hesitate to accept the opinion that the use of alypin as a local anæsthetic is altogether free from danger. The examination of the sinuses by means of the X rays is clearly and fully described, but the value of this portion of the work would be increased if it were illustrated with actual skiagrams. The illustrations in general are fairly good and one or two of them are excellent. Fig. 6, however, does not, in our opinion, repay the skill and ingenuity which have obviously been expended upon its construction. We heartily agree with the author in emphasising the perils with which nasal obstruction and catarrh threaten newborn infants, and we commend his remarks upon this subject to the consideration of other rhinologists, many of whom, to judge by their silence, do not seem to appreciate its importance.

We observe that the author is silent regarding certain English views on the pathogenesis of atrophic rhinitis, and we are also constrained to note that the influence of some of the classical controversies on rhinology in our country has not yet reached him. Simple nasal polypus, for example, is classified with neoplasms under the heading of fibroma. While this arrangement is not entirely indefensible we may be pardoned if we say that it might have been modified had the author been able to accept the opinions which have resulted from the developments of rhinological pathology in England. But the fact is that Dr. Zarniko has not felt the need of becoming acquainted with all the minutiæ of English and American investigations, so that the omissions we have just mentioned need not fill us with amazement. We have no doubt, however, that in future editions these omissions, dependent sometimes upon the dilatoriness of his English-speaking *confrères*, will be rectified.

These, to be sure, are but trivial faults. Otherwise, no book could be more thorough, more accurate, and, above all, more readable. The author's style is terse and pregnant, and presents a refreshing contrast to the vast and ponderous utterance in which Teutonic science has been known to veil itself. There is a good and trustworthy index, another novel feature in a foreign work, in which we have discovered only one slip (*Gaumenmandl, Hyperplasie*, 635, instead of 608).

We recommend every German-reading rhinologist to become possessed of this useful work, and we venture to express our conviction that its translation into English would meet with a ready welcome both in Great Britain and in America.

Le Diabète Sucré. (*Diabetes Mellitus.*) Par R. LÉPINE, Professeur de Clinique Médicale à l'Université de Lyon, Correspondant de l'Institut, Associé de l'Académie de Médecine, &c. Paris: Felix Alcan. 1909. Pp. 704. Price Fr. 16.

THIS important work contains a very careful study of diabetes mellitus and the problems involved in its pathogenesis, based upon 20 years' experimental, pathological, and clinical work by Professor Lépine and his pupils, among whom he mentions M. Porteret, M. Barral, M. Métroz, M. Martz, and especially M. Boulud. It opens with an interesting history of previous work upon the disease, in which due tribute is paid to the work of Willis, Dobson, F. Homes, and Rollo in this country. Dobson in 1775 appears to have been the first actually to separate sugar from the urine, and to maintain that it was not formed in the kidneys. The account given of the researches of Claude Bernard is lucid, interesting, and stimulating, being rendered more vivid by numerous extracts from the original papers. The extraordinary originality and fertility in resource of this brilliant investigator demonstrated the quantity of sugar in the blood, the presence of glycogen in the liver and its conversion into sugar, and proved that diabetes is a perversion of the normal processes of carbohydrate metabolism. Professor Lépine shows that Bernard failed to recognise the diminution of glycolysis in diabetes, and points out that in justice we ought not to forget the work of his opponents, notably Figuier, Pavy, and Schiff, which has been too much overshadowed by his glory. He proceeds to trace out the history of the discovery of the acetone bodies, and of the relation of the pancreas to the disease, and summarises the general history of diabetes down to the year 1892. Advances made since that time are regarded as contemporary and are included in the general text.

The first chapter deals with the sugar of normal blood, concerning which, both as regards its nature and its quantity, so much controversy has raged ever since 1847, the year in which Bernard commenced his researches. Its percentage, its distribution in the blood, and the question as to whether it exists free or in combination are all dealt with, and experiments in support of the statements made are quoted. Professor Lépine finds that the sugar of the blood as ordinarily estimated represents only a part of that actually present, since a considerable proportion of the sugar exists in a state of combination, from which it can be disengaged in response to the needs of the tissues. This sugar he refers to as "virtual sugar" (*sucre virtuel*). The processes of glycogenesis and glycolysis within the body are discussed at considerable length, and the conditions, favourable or otherwise, to their occurrence are categorically considered by Professor Lépine. The terms glycogenesis and glycolysis are

used in a restricted sense to indicate the production and destruction of sugar respectively within the body, and in order to avoid confusion the term zoamylin is adopted for the substance usually known as glycogen. This latter term has, however, been so long established that it may be doubted whether this terminology will be generally adopted. The general characters of glycolysis are admirably summarised at the end of a section devoted to its consideration. The use of sugar in the body to supply energy and heat is effected by means of glycolytic ferments or cytases which differ in different organs. The actual process of glycolysis is also multiform and is activated by the internal secretions of various organs, notably of the pancreas. In diabetes this process is diminished.

The conditions under which sugar appears in the urine are described in great detail, including the experimental forms, such as those due to adrenalin, to phloridzin, and to extirpation of the pancreas. The light which they throw upon the utilisation of sugar within the economy and of the disturbance of these processes in disease justifies the author's elaborate treatment. Professor Lépine uses the generic term glycuria instead of glycosuria to indicate the occurrence of any sugar in the urine, the latter term being restricted to the presence of glucose. Rather more than half of the book is devoted to the study of the physiological and experimental considerations which we have briefly enumerated, the remainder being devoted to a study of the phenomena of diabetes as met within man.

Professor Lépine maintains that under the generic term of diabetes mellitus a number of different pathological states are included. These he endeavours to separate in so far as our present knowledge enables this to be done. He is careful to point out, however, that a classification according to the organ chiefly involved is not a satisfactory one, since it offers no explanation of the actual pathogenesis of the condition and may group together forms which are fundamentally different. He suggests a provisional separation into two groups—first, those which increase the production of carbohydrates within the economy and which oppose their deposit in the form of reserve carbohydrates or fats, and secondly, those which diminish the destruction of sugar. Clinically, the task of discovering the particular form is often difficult, and the problem may not be completely solved even at necropsy.

The description given by Professor Lépine of the symptomatology of diabetes leaves nothing to be desired. It is clearly arranged, and affords an exhaustive study of the numerous symptoms and complications. The morbid conditions found in the various organs in diabetes are also described, and their significance in regard to the symptomatology and pathology is critically considered. An interesting chapter entitled "Nutrition in Diabetics" contains a study of the capacity of patients to utilise the various proximate principles of food. The conditions of acetonæmia and coma are dealt with fully and the theories put forward in explanation are discussed. Diagnosis and prognosis are systematically treated, and the influence of various symptoms upon prognosis receives due consideration. In regard to treatment, regimen and diet are fully discussed and the effects of various medicaments are reviewed. The manner of treating complications is also thoroughly worked out.

Professor Lépine's book forms an authoritative work of reference on the subject of diabetes. It contains very numerous references to the work of other authorities, and also the records of the experiments of Professor Lépine and his pupils.

Allen's Commercial Organic Analysis. Vol. II. Fourth edition. Entirely rewritten. Edited by HENRY LEFFMANN, M.A., M.D., and W. A. DAVIS, B.Sc., A.C.G.I. London: J. and A. Churchill. 1910. Pp. 520. Price 21*s.* net.

THIS volume will certainly be one of the most valuable of the set, since it deals with the important series of compounds, the fixed oils, fats and waxes, butter-fat, soap, glycerine, and so on. The choice of writer has again fallen upon well-known authorities upon each subject, Mr. C. Ainsworth Mitchell, B.A., F.I.C., contributing the articles on Fixed Oils, Fats and Waxes, and Lard; Mr. Leonard Archbutt, F.I.C., the article on Special Characters and Methods; Mr. Cecil Revis and Mr. E. R. Bolton on Butter Fat; Mr. C. A. Klein the article on Linseed Oil; Mr. W. Robertson the article on Higher Fatty Acids; Dr. H. Leffmann the article on Soap; Mr. W. A. Davis the article on Glycerol; Mr. John Addyman Gardner the article on Cholesterols; and Mr. Augustus H. Gill the article on Wool Fat, Cloth Oils. The fact that these gentlemen are authorities on their subjects appears from the copious references to their original researches in the text and in the foot-notes. Moreover, the records of scientific work quoted are of recent date. The reader will be impressed also with the amount of work contributed upon the chemistry and analysis of fats and their allies by Mr. Otto Hehner, with whom Mr. Ainsworth Mitchell often appears as collaborator, and by Mr. Julius Lewkowitsch. It is quite obvious that a large section of the subject-matter is of concern to our profession, because there are analytical methods set out which are directed to the detection of adulterants and impurities in certain substances used in medicine, as, for example, castor-oil, cod-liver oil, almond oil (fixed), glycerine, wool-fat, lanolin, and so forth, and it follows that the work is not restricted to giving a series of analytical methods to be used merely as assay methods for commercial requirements. The writers have included also methods of examination which by their application may bring fraud and objectionable practices to light. In addition, therefore, to the analyst engaged upon commercial work, the public analyst who is engaged in that important department of public health administration, the maintenance of a pure and uncontaminated food-supply, will find trustworthy counsel of particular concern to himself in the pages of this work.

The series has opened thoroughly well, and if the succeeding volumes maintain the thorough character of Vols. I. and II., the science of analytical chemistry will receive a decidedly rich addition to its literature.

LIBRARY TABLE.

Emergency Surgery for the General Practitioner. By JOHN W. SLUSS, A.M., M.D., Professor of Anatomy, Indiana University School of Medicine; formerly Professor of Anatomy and Clinical Surgery, Medical College of Indiana; Surgeon to the Indianapolis City Hospital, &c. Second edition, revised and enlarged. With 605 illustrations, some of which are printed in colours. London: Rebman, Limited. 1910. Pp. 748. Price 15*s.* net.—In times of stress the surgeon has little opportunity of consulting works of reference. If he be much accustomed to operative work, as are those who specially devote themselves to this class of practice, his memory will serve to tell him what to do. But if he be in general practice the lack of opportunity of dealing frequently with important and urgent conditions will render it very difficult for him to be sure that he is choosing the best methods of treatment. He has usually no time to search widely in his library for the information which he so earnestly requires. Many of the works on surgery may not present the information, even if they contain it,

in a form in which he can readily assimilate it, and therefore it should prove very useful for a general practitioner to have within reach a work which contains in one volume all, or nearly all, that he will immediately require in an emergency. We consider this book to be well calculated to fulfil the objects with which it has been written. The author makes no pretence of originality. The substance of his work is founded upon the received text-books; he has ranged widely in making his choice, and the result is good. It is always difficult in drawing up a guide for the performance of operations by those who are not much accustomed to practise operative surgery to know exactly where to draw the line between operations which may reasonably be undertaken by the general practitioner and those which should, whenever possible, be left to the operating surgeon. Circumstances alter cases; in a thickly inhabited country and in towns the general practitioner will restrict his operative work according to his own bent and his patients' wishes, for it will always be easy for him to invoke the aid of someone of special experience in each department of surgery. But in remote parts of the country, and especially in sparsely inhabited lands, the choice will lie between performance of the operation by the general practitioner and no operation at all. Therefore, it is justifiable, in a text-book like the present, to include some operations which can hardly be looked upon as suitable in ordinary circumstances for performance by those engaged in general practice because of the familiarity with an unusual technique that is required. The illustrations in the book deserve a few words. They are very numerous; for the most part they have been borrowed from other works and they have been selected judiciously; but though the author has been careful to assign the source from which he has taken the illustrations, yet that source has itself presented sometimes as original an illustration that was only borrowed. Thus on p. 266 we find an illustration of dislocation of the jaw, and after the title we find (Moullin), indicating the name of the author of the book from which it has been taken, but this illustration originally appeared in Sir William Fergusson's Surgery. Similarly we find modern origins attributed to four pictures showing the attitude assumed in the dislocations of the hip, which pictures originally appeared in Sir Astley Cooper's well-known work. The few original illustrations have been taken for the most part from photographs, and answer their purpose well.

Visiting Nursing in the United States. By YSSABELLA WATERS. New York: Charities Publication Committee. 1909. Pp. 367. Price $1.25.—The bulk of this volume is sufficiently described by the subtitle on the title-page, "A Directory of the Organisations Employing Trained Visiting Nurses, with Chapters on the Principles, Organisation, and Methods of Administration of such Work." The book is issued in the fiftieth year of anniversary of the establishment of the first systematic scheme of district nursing by the late Mr. William Rathbone, M.P., of Liverpool. The history of the evolution of district nursing forms one of the most interesting chapters in the sympathetic and careful memoir of William Rathbone, written by his daughter six years ago. The movement was originated within the Society of Friends, and Mr. John Cropper, the Quaker father-in-law of Margaret Macaulay, was Rathbone's chief coadjutor in the work. In the United States the system of district nursing did not attain any influence till 1877, and was first begun by missionary efforts in New York. A perusal of the directory portion of this volume shows the large development which the organisations have attained. If the inception of district nursing was British, there is no question that in America there is a completeness of organisation in this important social machinery from which we might derive many valuable hints. Miss Waters's volume will be very useful to members of committees and superintendents of home nursing work. The information is carefully arranged and simply compiled, the introductory chapters are admirably written, and the book is free from the sentimentality which often disfigures such works.

Dental Medicine: A Manual of Dental Materia Medica and Therapeutics. By FERDINAND J. S. GORGAS. Eighth edition. Manchester: John K. King. Pp. 627.—The present edition of this book should form a most useful addition to the library of the dental practitioner. The description of the various drugs is excellent, and to each the author adds a list of dental formula. About 40 pages of the book are devoted to the diagnosis of mouth affections, and although the information given is in many places useful, it is at the same time occasionally open to criticism. For example, modern opinion is hardly in agreement with the view that dental caries is "caused directly by micro-organisms which attach themselves and grow in contact with the surface of the tooth, being protected by a gelatinous film, and forming an acid which acts upon the tooth tissue, and thus affords access to the micro-organisms." In dealing with the important question of hæmorrhage after extraction of the teeth, there is no mention of that most useful drug, calcium lactate. The information, too, on the treatment of pain following tooth extraction would have been more useful if it had been a little fuller. By these criticisms, however, we do not wish to detract from the useful character of the book.

The Pharmacopœias of the London Hospitals. By PETER SQUIRE. Eighth edition. Revised by PETER WYATT SQUIRE. London: J. and A. Churchill. 1910. Pp. 496. Price 5*s.*—There is no question of the practical value of a book which presents an exhaustive comparison of the Pharmacopœias of the London Hospitals. It is obvious that in such institutions the formulæ are selected for exalted reasons and the judges represent necessarily the leading authorities on therapeutic and pharmacological questions. The seventh edition of this work was published in 1900, since when, it is important to note, no less than 26 of the London hospitals have produced new editions of their Pharmacopœias. The alterations thus involved have, of course, rendered the old editions out of date, though unchanged in many regards. The popularity which the work enjoyed ten years ago called for a fresh edition in which the indicated revisions should be made. The present issue, therefore, has practically been rewritten, and to-day both prescriber and dispenser may consult its pages with profit and interest, remembering that the formulæ contained represent, by studied selections and combinations of drugs, the views of a great tribunal on treatment, brought carefully up to date. The important question of nutrition in disease is not overlooked, and instructive comparisons are made between various peptonised foods, nutrient enemata, and so forth.

Chats on Astronomy. By H. P. HOLLIS, President of the British Astronomical Association. London: T. Werner Laurie. Pp. 226. Price 3*s.* 6*d.* net.—In that interesting work, the second book of Esdras, it is recorded that the angel asked Esdras three questions concerning the wind and the fire and the day "wherethrough thou hast passed"; and when Esdras expressed himself as being unable to answer, the angel replied, "Thine own things that are grown up with thee canst thou not know." Now this answer is eminently typical of the knowledge of the average man as regards astronomy, especially of the motions of the stars and the moon, which he has seen so many times during his life. Mr. Hollis's unpretending little book will

give such a man a very clear and simple explanation of various astronomical phenomena, and the reader who masters it will no longer be puzzled to know whether the full moon is seen in the west at sunset or in the east, and he will also be able to appreciate to the full such absurdities as were recorded in a well-known novel where an eclipse of the sun was made to take place on the day of the full moon and to last over an hour. The book is illustrated with pictures and diagrams, and three of the latter are specially valuable—namely, those which show the horizons at various parts of the earth's circumference. Halley's comet has from a spectacular point of view been a disappointment, but the reader will find an excellent account of it in Mr. Hollis's book.

New Inventions.

A COMPLETE PORTABLE SET OF APPARATUS FOR THE RAPID QUANTITATIVE ANALYSIS OF THE URINE AND THE GASTRIC JUICE.

WE have received from the Roborat Company, of 8, Harp-lane, London, E.C., a complete set of analytical apparatus designed for the quantitative estimation of the significant constituents of urine and of the gastric juice. The set provides for the following estimations in regard to urine: Albumin (phospho-tungstic acid precipitation), sugar (fermentation method in an ingeniously designed tube), uric acid (absorption of iodine), urea (in an approved form of ureameter), acidity (the addition of an alkali in a graduated tube termed the uracidimeter), phosphates (precipitation as magnesium ammonium phosphate in a "phosphatometer"), indican (by formation of indigo with perchloride of iron, subsequently dissolving the indigo in chloroform), sulphates (by precipitation with barium chloride, the insoluble sulphate of barium being measured in a specially designed tube),

ammonia (by adding neutral formaldehyde solution to neutralised urine and determining the acidity produced by the reaction of formaldehyde with ammonia), ethyl-diacetic acid, specific gravity, and so forth. The tests for the gastric juice are for the most part qualitative, but a tube called the "quantitest acidimeter" is employed for determining the acidity of the gastric juice by a simple and rapid method. We have tested the apparatus in regard to its accuracy on carefully prepared standard solutions respectively of albumin, uric acid, sulphates, phosphates, and weak hydrochloric acid. The results were accurate, although the procedure proved at first to be a little difficult owing to a want of clearness in certain of the instructions given. In the estimate of the total sulphates, for example, no time limit is given for the aggregation of the barium sulphate, while in the estimation of phosphates a specified time for depositing is properly mentioned. The paragraph on phosphates is not clear in regard to making an allowance for dilutions in the table recording the quantity of P_2O_5 corresponding with the mark on the tube. It is not stated whether the calculations give P_2O_5, but we found by a practical test that that is the case, while in the sulphate test the results are evidently recorded as sulphur and not SO_3. It must be remembered that the medical man has not always the facilities or the experience of an analytical chemist, and therefore the instructions for the use of analytical apparatus for diagnostic purposes should be very clear and incapable of misinterpretation. We have, however, proved the utility, accuracy, and convenience of this set of apparatus for the quantitative analysis of urine, and with the instructions as to manipulative procedure rendered in clear, unmistakeable terms, there can be little question as to its value in diagnosis to the medical practitioner.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 16th, 1832.

FRACTURED RADIUS *v.* DISLOCATION OF THE WRIST.[1]

A man was admitted into the hospital with fracture of the radius just above the carpus. Mr. Fernandez had put on two splints and a bandage, and slung the patient's arm to his side in the usual manner. Mr. Brodie, however, took these off and said, "Gentlemen, this is a case of what they call dislocation of the wrist, and, strange to say, books and authors of the present day, even down to Sir Astley Cooper, still speak of dislocation of the wrist; now, for my own part, I never saw such a thing, nor do I think such a thing can occur, for in the wrist the ligaments are much stronger than the bones, and, therefore, where any force was used, the bones would certainly give way first.

Now, I will show you the way in which I do up these fractures; it is a plan too which I have always followed with success. You see that here is one projection below, arising from the dropping down of the fractured end of the radius, and here is another projection above, of the carpus. Well, now, I put a compress above and below on each of these projections, then I put a piece of strapping to each; the piece of strapping below I fasten over the splint above, and the piece of strapping above I fasten under the splint below, and thus steadily confine them, and then I put a roller over the whole. When the man's arm was thus put up, he expressed himself much easier. "About ten years ago," said Mr. Brodie, "a man came into the hospital, with a very severe accident. I believe it was an injury of the head, a compound fracture, or something of the kind. However, this man had two large bulging lumps, one above the wrist and the other below the radius. On examining the body after death, I cut across the muscles and tendons, and there I found a large quantity of extravasated blood; and down dropt the hand, and there was a fracture of the radius, just as in this case. A medical gentleman once sent to me to say, that he had a case of dislocated wrist, which he could not reduce, and from his description I was led to believe, that it was a subluxation. This patient died, and the medical gentleman examined the body; and on opening the wrist, he found just such a fracture of the radius as this."

To some remarks from some of the pupils who said they had seen a child's wrist frequently dislocated, Mr. Brodie said, "that such cases might be, but that he had never seen them;" adding, "Indeed, I believe Dupuytren says he never saw one."

[1] Clinical Remarks made by Mr. Brodie at St. George's Hospital, May 31st, 1832.

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1910.

The Midwives Act Amendment Bill and the Incorporated Midwives Institute.

WE have received from the Incorporated Midwives Institute a copy of a letter which has been addressed to Lord WOLVERHAMPTON, in the character of Lord President of the Council—a post which he has just resigned—and enclosed with this is a copy of the amendments which the Midwives Institute desires to see introduced into the Bill. Those particularly interested in the matter will have in their hands the text of the Bill or will remember the summary of it published in THE LANCET,[1] and we print the suggested amendments on another page (see page 1728) in order that they may be able to apprehend clearly what these imply. At least one of these amendments deals with a question of considerable difficulty for which there is little chance of a solution satisfactory to all, and some of the others are likely to provoke divergence of opinion. They are put forward by an organisation rightly acting in what it believes to be the true interests of a very large body of practising midwives, and they have every claim for careful consideration. If we criticise them from the point of view of the members of the medical profession, we do so in no hostile spirit, while we must ask our readers to bear in mind present conditions, and their probable or, we may say, certain development. The training and registration of midwives and certain consequences arising therefrom, some of which are undoubtedly and regrettably prejudicial to the medical profession, are and will remain established facts in our civil life. That is to say, the law will continue to provide for the training and enrolling of midwives who are to have the care of mothers of the poorer classes in cases of normal childbirth, and will compel these midwives in certain emergencies to refuse to treat their patients unaided and to summon a medical man. Provision will apparently now be made for the remuneration of the medical man so called in, and there will be as time goes on an increasing supply of efficient midwives under a system from which mothers and children belonging to the humbler classes of the community will, it is hoped, derive considerable benefit. There will follow from this, however, almost certainly a diminution of the earnings of a large class of medical men from the practice of midwifery, and we must regard this circumstance as practically inevitable when discussing the Bill before Parliament and the amendments of the Incorporated Midwives Institute. All this was fully recognised in our columns when the Midwives Act of 1902 was struggling to become law.

The most important question raised is undoubtedly that of the remuneration of the medical man called in to assist the midwife. Ought the public body responsible for this to be the local supervising authority or (as provided by the Bill) the board of guardians? We are on the whole inclined to think that it should be the former, but we state briefly what appear to us to be the principal points for consideration on both sides. The object of the legislation in question is to ensure the bringing of children into the world under the best conditions reasonably obtainable for them and for their mothers. The local supervising authority is charged with the superintendence of these conditions in every respect so far as the work of the midwife is concerned, including the enforcement upon her of the law with regard to the summoning of the medical man. It seems to us hardly reasonable or businesslike to provide for the remuneration of the medical man in what must prove to be a large class of cases, and to place the duty of paying that remuneration to him in the hands of another body. We would point out that the guardians, to whom this duty alone in connexion with the furtherance of the policy of the Midwives Act is to be entrusted, are not interested in the fulfilment of the conditions necessarily precedent to the payments, and have other interests and responsibilities making a first call upon their attention. There has been a certain amount of experiment already in this matter, and we are of the opinion that the majority of the medical practitioners likely to be affected would rather find themselves looking for their fees to the local supervising authority than to the board of guardians, and that there is a good deal of force in the contention that the parents concerned would regard the intervention of the guardians through their relieving officer with distrust and dislike, a state of affairs which would be prejudicial to the mothers and children for whose benefit the Act was passed. On the other hand, there is the argument, which is entitled to the fullest consideration, that the inquiry into means which the guardians would have the power to make, and which they probably would make more searchingly than the local supervising authority, would do something towards checking a growing reliance upon public aid in matters where the individual ought to be compelled to retain his independence and to help himself. In this connexion, and from the point of the medical profession it may be argued that the intervention of the guardians might render the employment of the midwife less general, and that local medical practitioners would benefit. The whole question is one of great difficulty, and as we have submitted it may be impossible to find an answer to it completely satisfactory either to the medical profession, the midwives, or the public.

The next most important point raised by the Midwives Institute is with regard to clause 11 (i.) of the Bill, which proposes that "where a woman certified under the principal

[1] See THE LANCET, April 9th, 1910, p. 1039, et seq.

Act who has not given to the local supervising authority such a notice as is mentioned in section 10 of the principal Act [1] attends any woman in childbirth in any capacity other than that of a midwife, and a duly qualified medical practitioner is not present at the time of the birth, she shall, within 48 hours from the birth, give to the local supervising authority notice in writing of the fact that she so attended ....." From the point of view of the midwife this is objectionable because it would tend to prevent the employment by medical men of midwives as monthly nurses, in cases where the midwife, because she does not practise as such, has not given notice of an intention to do so. There is considerable force in this contention. Under the proposed clause a medical man might arrive at his patient's bedside to find that delivery had taken place five minutes before in a satisfactory manner, but that the nurse engaged was compelled either to lay herself open to a fine of £5 or to report his absence to the local supervising authority. Unless very good reason can be shown for the insertion of this clause, the evasion of which would be easy if not frequent, we agree with the Midwives Institute that it might well be omitted. But with the amendment to Clause 13, another important modification proposed by the Midwives Institute, we are not so much in accord. The amendment suggests that whereas Clause 13 of the Bill seeks to enable a local supervising authority to aid the training of midwives, it should also be empowered to make grants in aid of their maintenance. We question the desirability and the justice of stimulating artificially the supply of midwives by a State "bounty system." If midwives ought to be subsidised in the practice of midwifery, why not medical men? And yet if there had been a proposal made before the passing of the Midwives Act that the local authority should pay salaries to local medical men in consideration of their attending confinements at reduced fees it would have been condemned beyond doubt as tending to deprive the working classes of habits of thrift and independence, and as a suggestion for remunerating a particular profession at the expense of the ratepayer. Any such maintenance as that proposed should, in our opinion, be left to voluntary benevolent agencies. The other amendments concern midwives rather than the medical profession. Their demand for more representation upon the Central Midwives Board than is proposed by the Bill is not unreasonable, and the other topics to which they call attention relate to questions of administration and discipline as to which we do not feel called upon to express opinions.

Roman Medicine.

AN interesting contribution to the history of medicine is afforded by a book recently published by Dr. THEODOR MEYER.[2] We welcome the book because we believe that the study of the evolution of our science is not only interesting but valuable. Ancient medicine had its great discoveries, opportunities, schisms, and set-backs. By observing their influence upon the science of medicine as a whole we may hope to avoid pitfulls into which our forefathers fell. Dr. MEYER points out that but little is known of the medicine of the Romans in the early republican period, except that it was practically no more complex than that of primitive races, consisting chiefly of domestic remedies of simple character and of superstitious observances. It is remarkable that this simplicity should have persisted for so long, and the explanation of Dr. MEYER is that the prejudice of the Romans against technical professions and business of any kind hindered development. It was in the end the closer relations with Greek culture which gave the first impulse to the development of medicine on Roman soil, but even then the practitioners of medicine in Rome were for many years simply Greek slaves. This was due to the fact that free Greek physicians refrained from proceeding to Rome owing to the extremely unfavourable judicial and social treatment offered to foreigners by the Romans. As a result, the *servus medicus* became an essential feature of the household of most of the richer Romans. The natural consequence of the practice of medicine by persons of humble station and origin was that it was largely a matter of domestic remedies, since the scientific developments of Greek medicine were beyond the capacities of the Greek slaves. This is well demonstrated in the receipt-book of CATO the Censor, in which side by side with measures such as pomegranate for the treatment of worms and juniper in the treatment of urinary difficulties, there occur incantations and exorcisms against sprains and also other superstitious formulæ. When at length Greek learning and philosophy received encouragement at Rome it was chiefly rhetoric and jurisprudence which were studied at first, but later the cultured Roman began to include science within his purview, and thus medicine began to be studied, as may be seen in the encyclopædic works of VARRO, CELSUS, and others.

At first such study led to but little, if any, advance in the practice of medicine, which still remained in the hands of the humbler classes. The first attempt of free Greek physicians to settle in Rome towards the end of the third century B.C. failed, but during the course of the second century matters changed. Rome evolved from a simple capital to the world's metropolis, a proletariat large in comparison with the well-to-do citizens arose, and freed slaves began to practise medicine; moreover, the prejudice against paid professions began to lessen. Later, the bestowal by CÆSAR of citizen rights upon all free foreign physicians practising in Rome gave a further impetus to medical science which the pioneer work of ASCLEPIADES had given to Rome. When he began in about the year 90 B.C. to introduce a higher medicine to the Romans he had to contend against the popular character of its practice on the one hand, and the abstract interest taken in medicine as a science by the educated Romans on the other. He grafted his medical teaching upon the fashionable Epicureanism of the time, and thus afforded the Romans a scientific medicine after their own taste, and at the same time he reformed the practical treatment of disease. He opposed

[1] Notice of intention to practise in any area.

[2] Theodorus Priscianus und die Römische Medizin, by Dr. Med. et Jur. Theodor Meyer, Privat-Dozent für Geschichte der Medizin an der Universität, Jena. Jena: Gustav Fischer. 1909. Pp. 352. Price, bound, 8 marks; paper cover, 7 marks.

polypharmacy and the excessive use of emetics and purgatives, but encouraged a natural treatment by means comprehensible by the people. According to Dr. MEYER, his personality was also an important factor in his success. He describes him as a mixture of a thoughtful scientific physician and an experienced practitioner with a slight tinge of charlatanry. The further development of medicine upon the foundations laid by ASCLEPIADES soon occurred. A successful cure of AUGUSTUS by MUSA led to an advancement of the free practitioners in Rome to the knightly class and full citizen rights, with the result that the Romans themselves in increasing numbers adopted the medical calling. THEMISON, the most distinguished pupil of ASCLEPIADES, was the founder of the Methodical school, which exerted its influence for more than four centuries and reached its highest development in the work of SORANUS. In the teachings of ASCLEPIADES there was only a superficial compromise between the two divergent aspects of medicine, the theoretical and the practical. THEMISON endeavoured to find certain general indications of disease, and discovered, as he believed, that, stripped of accidental or non-essential features, they all showed certain simple common, general features, more especially in regard to the conditions of the secretions and excretions. In explanation of this he adopted the view of ASCLEPIADES in regard to the "pores" of the body, which were regarded as interstices between the solid constituents, these being regarded as composed of atoms. THEMISON separated three states—a "status strictus," in which the pores were constricted; a "status laxus," in which they were relaxed; and a "status mixtus," in which both conditions co-existed in different parts of the body. Dr. MEYER emphatically denies the view which is now often expressed that this doctrine of the common features of diseases was the sum and substance of Methodism. It was, he maintains, merely the basis upon which the Methodists built up and evolved their methods of treatment. They dealt but little with considerations of anatomy and physiology, and they concerned themselves with the study of causation less, or, as in the case of THEMISON, not at all. On the other hand, they went deeply into matters of pathology, symptomatology, and treatment; indeed, Dr. MEYER characterises their descriptions of disease as revealed to us in their writings, more particularly those of CÆLIUS AURELIANUS, as masterly. Their treatment was based upon their theoretical conceptions of disease, the "status strictus" being dealt with by relaxing agencies, and so forth, but they also were the first to differentiate between acute and chronic diseases and to modify their treatment accordingly. Moreover they did not confine themselves to a system of general treatment, but adopted measures for the relief of symptoms, not necessarily suggested by the "status" of the patient.

The long duration of Methodism depended upon its emphasising the practical aims of medicine, and in this connexion Dr. MEYER endeavours to vindicate the good name of a much-abused disciple of Methodism, THESSALUS of Tralles, who is quoted by GALEN as affirming that he could teach the art of medicine in six months. Dr. MEYER maintains that in this apparently boastful claim he only meant that he could impart the theoretical basis of medicine in that period, for he laid great stress upon the practical demonstration of disease and its treatment, and was, in fact, the first to deliver systematic instruction at the bedside. SORANUS appears to have done most to bring together the practical tendencies of the Romans and the scientific principles of the Greeks. He was perfectly educated in anatomy at Alexandria and was well versed in physiology, but he adopted the views of the Methodists, and his works demonstrate more than those of any other writer the catholicity and adaptability of this school. The great influence of the Methodical school even in its early period is demonstrated in the writings of CELSUS, which afford a clear view of the state of medicine in Rome in the middle of the first century A.D. Rome was at this time the arena for all philosophical and metaphysical contests, the practice of medicine was for the most part in the hands of trained physicians, but the old institution of the *servus medicus* still lingered, and some of the educated laity studied medicine, among them CELSUS. His work was simply a critical and eclectic review of the scientific medicine of his time. This is the reason that his writings are ignored by his contemporaries and why he exerted no influence upon Roman medicine. A similar review of the common or domestic medicine of the second half of the first century is afforded in the writings of PLINY, showing the mixture of the rational and the superstitious, in which the original popular factors can be differentiated from the Greek and Oriental additions. PLINY'S aversion to the Greek physicians and his neglect of their methods serve also to indicate the opposition which the inquiring minds of the cultured physicians had to contend against. One striking feature of the Roman medicine of the Imperial period is its practical character and the large number of the various recipes and directions for treatment. Although a pneumatic school arose in opposition to the Methodists, after the teaching of ATHENÆUS, and although its tenets were adopted by HERODOTUS and ARCHIGENES, amongst others, the therapeutic principles of the Methodists were more or less generally adopted, and their influence is visible even in GALEN, the champion of eclectic principles.

In summing up the influence of this remarkable man Dr. MEYER epigrammatically remarks that "GALEN was for mediæval medicine an epoch, for Roman times merely an episode." This he attributes to his endeavour to raise medicine from the grade of an art to that of a science. He was an investigator rather than a practitioner, whereby the practical was less in the foreground of his work, thus rendering his views foreign to the practical minded Romans. As Dr. MEYER sagely observes, it demonstrates the power of the Methodists that GALEN, who afterwards dominated mediæval thought for a thousand years, fought against its tendencies in vain in his own lifetime. After GALEN, a decline in medicine as a science occurred side by side with a decline in all branches of the higher culture. Later writings often consist of compendia of treatment—some prepared to supply the needs of a non-medical public, others for the use of physicians. Among these works may be included the writings of RUFUS, who probably lived in Rome in the time of TRAJAN, a work of ATHENÆUS, the "Compositiones" of SCRIBONIUS LARGUS,

and the Euporista of THEODORUS PRISCIANUS. It is this work to the consideration of which Dr. MEYER devotes his book. He gives a brief review of the few facts known about THEODORUS PRISCIANUS and translates the text of his writings into German. He was a pupil of VINDICIAN, who lived in the time of VALENTINIAN I., so that his work must belong to the end of the fourth century A.D. or the beginning of the fifth. Dr. MEYER agrees with VALENTINE ROSE that THEODORUS PRISCIANUS used the writings of GALEN as the basis of his own, more particularly in his first and second books. His third book was derived from SORANUS. He deals with external and internal diseases and with diseases of women. The only surviving fragment we possess of a fourth book gives some remedies against headache and epilepsy. Enough, however, remains of THEODORUS PRISCIANUS to warrant this introduction of him to our notice, while, as we have pointed out above, the study of the history of medicine should be part of the education of the cultured practitioner of medicine. Dr. MEYER'S book is a notable contribution to the history of Roman medicine. The subject has recently been before our readers in the interesting FitzPatrick lectures delivered before the Royal College of Physicians of London by Sir T. CLIFFORD ALLBUTT, and published in THE LANCET.[1] Dr. MEYER'S views seem to be in general accord with those of Sir CLIFFORD ALLBUTT, more particularly in assigning to ASCLEPIADES a higher scientific position than has generally been accorded to him. We commend Dr. MEYER'S book and Sir CLIFFORD ALLBUTT'S lectures to the notice of those interested in the history of medicine.

The Manchester Milk-supply.

THE control of the milk-supply, more particularly of that of large towns, is a subject of great significance in regard to the public health, and one with very important medical and economic aspects. It is a matter of distinct regret that administrative and political difficulties have so far prevented the adoption of general and uniform measures to ensure a satisfactory solution of the problem. It is therefore of special interest to notice the results obtained by the enlightened and public-spirited endeavours of the Manchester Health Department to ensure, so far as is consistent with their powers, that the supply of milk to the city shall be free from the dangers of tuberculous infection. A valuable record of the measures adopted, and of the results obtained, is given in a report on the investigations in the public health laboratory of the University of Manchester upon the prevalence and sources of tubercle bacilli in cow's milk,[2] by Professor SHERIDAN A. DELÉPINE; in a paper read by him before the Manchester Statistical Society on Nov. 10th, 1909, on the Manchester Milk-supply from a Public Health Point of View; and in a paper published in THE LANCET of May 14th, p. 1326. The history of the movement is briefly that in 1897, on the recommendation of Professor DELÉPINE and as a result of his observations on milk from tuberculous cows, Dr. J. NIVEN, the medical officer of health of Manchester, made arrangements for inspecting, and as far as possible controlling, the sources of the milk-supply, utilising the powers afforded under the Infectious Diseases Notification Act, 1890. The work was carried on tentatively for two years, but in 1899 the Health Department put in effect the powers obtained under the Milk Clauses of the Manchester General Powers Act, 1899, and has since systematically supervised the milk-supply. Professor DELÉPINE'S papers give a *résumé* of the work done since that time.

Samples of cow's milk intended for consumption are obtained at the railway stations or elsewhere within the city by the food and drugs inspectors under special precautions devised by Professor DELÉPINE and are submitted to bacteriological examination. All samples found to be capable of producing tuberculosis are traced to their sources by the medical officer of health and the veterinary surgeon. The latter inspects the cows on the farms sending tuberculous milk, and takes samples of the milk of each cow that appears to be tuberculous. The samples are tested in the public health laboratory, and when the milk of a cow proves to be tuberculous the farmer is required by the medical officer of health to isolate the affected cow, and is advised to have the animal slaughtered in the presence of the veterinary surgeon, advice which is generally followed. The methods adopted for the examination of the milk are the measurement of sediment or "slime" obtained by centrifugalisation, the microscopical examination of small portions of this sediment for cells, bacteria, and other foreign bodies, and inoculation experiments to determine whether virulent tubercle bacilli are present. The population of Manchester was 643,158 in 1908, and it is calculated that in the same year 62,000 gallons of milk entered the city daily. Some idea of the magnitude of the work involved in testing the milk may be formed from the facts that during the 12½ years, 1897 to 1909, with which the report deals 4997 samples were taken from cans of milk arriving in Manchester and 1048 samples of milk were collected at the farms from individual cows. Various charts and maps were prepared to indicate the districts from which the tuberculous milk was obtained, and on examining the conditions prevailing in the farms in these places it was found that the retention of old stock and unsatisfactory housing of the cattle were commonly present. In young cattle tuberculosis is seldom extensive, but as age advances numerous organs become attacked, including the udders. That the measures adopted have been productive of good is shown by the fact that the percentage of samples of milk collected at the railway stations found to be tuberculous has diminished; thus during 1897–1898 the percentage was as high as 17·2, while during 1907 it was 5·7, in 1908 it was 8·9, and in the first half of 1909 it was as low as 3·8. Repeated examinations of certain farms showed that the disease tended to recur in some of them even after a comparatively long period of freedom. Professor DELÉPINE states that the disease may reach the udder of one cow from another, while it is obvious that some farmers will buy inferior stock, which is not infrequently diseased; therefore he urges that so long as drastic measures for the eradication of tuberculosis in cattle are not adopted frequent inspection of farms is a necessity to secure a milk even comparatively free from tuberculous infection. In regard to the care of the milk after milking,

[1] THE LANCET, Nov. 27th, 1909, p. 1565.
[2] Extract from the Annual Report of the Medical Officer of the Local Government Board for 1908–1909. London: Printed for His Majesty's Stationery Office. Darling and Son. 1910.

interesting observations are recorded upon the amount of sediment or "slime," and it appears that it is difficult to obtain milk containing on an average less than seven grains of sediment per gallon, and that ordinary milk often gives a much larger quantity. Judged by this standard, the cleanliness of the milk has distinctly improved during the period under consideration owing to the greater precautions taken to ensure cleanliness in the cowsheds, in the persons of the milkers, and in the subsequent handling of the milk. The farmer usually strains the milk before filling cans with it, and in some dairies the milk is centrifugalised, but, as Professor DELÉPINE shows, straining may be a source of contamination, since the strainers are seldom sterilised and dirt may accumulate in them. Centrifugalisation removes a great deal of dirt and extraneous matter, but some of the bacteria cling to the cream. It is, therefore, obvious that these measures are insufficient and cannot be relied upon. To ensure pure milk it is important to eradicate tuberculous animals from the herds and pay due attention to the state of the cows, the stables, dairy hands, and utensils, and to avoid possible infection during transit by contamination by flies or other agencies. It is also important when the milk has to come from a distance to keep its temperature as low as possible, refrigeration being the best safeguard against the multiplication of bacteria.

The diagnosis of tuberculous disease of the udder in cows is very important in regard to the prevention of infection of the milk, since when this lesion is present the milk is certainly infectious, and lesions of the udders were found in one or more cows on at least three-fourths of the farms supplying tuberculous milk to Manchester. Although other sources of infection are possible, since bacilli may be present in cases of bovine tuberculosis without clear affection of the udder, this is undoubtedly the cause in the great majority of instances. Unfortunately, the diagnosis is a matter of difficulty by inspection and palpation alone, since tuberculous and other forms of mastitis present practically identical characters, and it is, moreover, impossible by these means to discover early tuberculous lesions of the udder. The one certain criterion is that afforded by bacteriological examination and inoculation, and it is only by a combination of these processes with veterinary inspection that the necessary accuracy for public health administrative work can be obtained. The delay of 10 to 20 days entailed by inoculation methods is a weak spot in this procedure, since it appears that some farmers, warned by the sampling of the milk, take advantage of this delay to remove suspicious cows from their farms before the arrival of the veterinary inspector. Professor DELÉPINE has therefore attempted to improve the technique of his microscopical methods for the examination of unmixed milk taken direct from the cow, and he believes it is possible by microscopical methods to recognise tubercle bacilli in the milk of more than 90 per cent. of the cows that yield infected milk, and that the remainder could be detected by submitting all samples giving negative results to the inoculation test on guinea-pigs. The results obtained by the Manchester health authorities under the guidance of Professor DELÉPINE and Dr. NIVEN and their collaborators and assistants, to all of whom Professor DELÉPINE acknowledges his indebtedness, are distinctly encouraging, and they should afford an interesting object-lesson to other local authorities and stimulate them to similar endeavours. That it is of the utmost importance that similar measures should be adopted generally is shown by the fact that it had been found that some of the farmers, after it was discovered that the milk they had been sending to Manchester was tuberculous, sent it elsewhere or used it to make cheese. Since it is now generally accepted that bovine tuberculous disease is communicable to man, and that tuberculous meat and milk are sources of danger, general precautions should be adopted as soon as possible. The complete eradication of bovine tuberculosis should be the ultimate aim as a prelude to the eradication of the disease in man, but since this is at present a counsel of perfection the most strenuous efforts should be made to avoid infection of the milk, and in their serious endeavours towards this object we may heartily congratulate the Manchester health authorities and their scientific advisers.

Annotations.

"Ne quid nimis."

THE LEGISLATURE AND THE PROBLEM OF THE FEEBLE-MINDED.

THE letters which have recently appeared in the *Times* and elsewhere over the signatures of the Bishop of Birmingham and other well-known persons, and which have called forth strong expressions of agreement from representative men throughout the country, should arouse the Government to a sense of the feeling, entertained by those who are competent to judge, that it is high time for legislative action to be taken on the lines laid down by the report of the Royal Commission on the Care and Control of the Feeble-minded. As it is very justly pointed out by Dr. Gore and his fellow signatories, the present moment, when the controversial issues which ordinarily divide parties and which consume so much Parliamentary time are of necessity laid aside, is peculiarly opportune for bringing forward a comprehensive scheme of reform to deal effectively with this problem of the feeble-minded, which in its bearing on the present and still more on the future well-being of the nation is very certainly of far more urgent importance than most of the questions that figure so prominently in election addresses. The proposals of the Royal Commission have now been before the public for nearly two years, and during that time they have met with a measure of approval from informed opinion, which is almost without record in the history of social legislation. Not only have the main lines of the Commissioners' plan been accepted as sound and practicable by the large majority of the experts who have had to do with this particular problem, but they have also been endorsed in important reports which have recently appeared dealing with somewhat related questions—viz., in the two reports of the Poor-law Commission and in the report of the Departmental Committee on the Inebriates Acts. While this fact affords strong confirmation of the value of the suggested method of dealing with the problem of the mentally defective, it is perhaps still more important as indicating the close connexion of that problem with a variety of other social questions on which it exercises a very disturbing influence. The feeble-minded, as we are told in the Majority

Report of the Poor-law Commission, constitute one of the greatest difficulties in Poor-law administration; their presence in large numbers amongst the inmates of the inebriate reformatories has been a chief cause of the miscarriage of the Act of 1898; as petty delinquents they are a source of trouble and disorder in prisons; while to the educationist they are, under present conditions, little more than an occasion for what he knows must be utterly wasted effort. But if the delay in grappling with the problem of the feeble-minded interferes in this way with the working of the existing machinery in these different fields of administration, it has an even more serious effect through the obstacles which it places in the path of reform. The administrative machinery for these various ends cannot be developed and specialised on the lines necessary to make it fit the requirements of modern conditions without such progress rendering it still less suitable for the feeble-minded paupers, or the feeble-minded inebriates, or the feeble-minded criminals, as the case may be, who in the present chaotic state of things would fall under its operation. And so it comes about that in these several social questions the inherent difficulties which help the forces of inertia are strengthened by the presence of this disturbing factor common to them all. On this ground it may be confidently asserted that the problem of the feeble-minded is of special and peculiar urgency, not only by reason of its intrinsic importance, but also because its solution on the lines of the comprehensive scheme recommended by the Royal Commission would do so much to clear the way for social reforms in other directions. By bringing all the various categories of defectives under the control of a single central authority such a scheme would relieve the other administrative organs of the State of work for which they are entirely unfitted, and would leave them free to perform their proper functions and to develop in adaptation and efficiency. At the present moment the force of this argument should be appreciated with special clearness, for it finds its most pertinent application in the case of the Poor-law, where some reconstruction is a matter of immediate necessity, and where such a reconstruction will be rendered very much easier if the mentally defective have ceased to be a factor in the problem. As matters stand, the feeble-minded tramps, the half-witted girls who drift about between the streets and the lying-in ward of the workhouse, and the rest of the defective population who have to be dealt with by the Poor-law authority are a serious impediment to the working of the administrative machinery; and, what is more, their inclusion in the category of the poor and destitute tends in no small measure to confuse and obscure the right conception of the purpose and function of the Poor-law, and is likely in this way to magnify the difficulties of what is already a sufficiently arduous problem. On every ground, therefore, of expediency, no less than of reason, it must seem clear that the adoption by the Legislature of the proposed scheme for the treatment of the feeble-minded would enormously facilitate the task of revising the Poor-law, and that it is, in fact, the natural and obvious preliminary to entering upon that task. The actual position of this question is in many respects unique; its extreme urgency is universally acknowledged; a scheme for its solution has been formulated after prolonged inquiry and consideration and has met with practically unanimous approval; and with the conditions thus ripe for Parliamentary action the accident of a political crisis affords an exceptional opportunity for immediate legislation. So rare an occasion should not be lost by legislators for whom the idea of social reform means more than a convenient theme for platform platitudes.

MEDICAL AND SURGICAL APPOINTMENTS TO THE KING.

THE following list of medical and surgical appointments to the King appears in the *London Gazette* of June 10th:—To be Physicians in Ordinary to His Majesty: Sir Francis Henry Laking, Bart., G.C.V.O., K.C.B., Sir James Reid, Bart., G.C.V.O., K.C.B., and Sir Richard Douglas Powell, Bart., K.C.V.O. To be Physicians Extraordinary to His Majesty; Sir Thomas Barlow, K.C.V.O., Bart., Sir William Henry Allchin, Dr. Bertrand Dawson, and Sir Alan Reeve Manby, M.V.O. To be Physician to His Majesty's Household: Sir Robert William Burnet. To be Sergeant-Surgeons to His Majesty: Sir Frederick Treves, Bart., G.C.V.O., C.B., and Sir Richard Havelock Charles, K.C.V.O. To be Honorary Surgeons in Ordinary to His Majesty: Mr. Rickman John Godlee, Mr. Anthony Alfred Bowlby, C M.G., and Sir William Watson Cheyne, Bart., C.B., F.R.S. To be Surgeon to His Majesty's Household: Mr. Hugh Mallinson Rigby. To be Surgeon Apothecary to His Majesty and to His Majesty's Household: Sir Francis Henry Laking, Bart., G.C.V.O., K.C.B. To be Surgeon-Oculist to His Majesty: Sir George Anderson Critchett, Bart., C.V.O. To be Laryngologist to His Majesty's Household: Mr. Milsom Rees. To be Bacteriologist to His Majesty's Household: Dr. Harold Robert Dacre Spitta. To be Dental Surgeon to His Majesty's Household: Mr. Charles Edwin Truman. To be Anæsthetist to His Majesty: Dr. Frederick William Hewitt, M.V.O. To be Chemist and Druggist to His Majesty: Mr. Peter Wyatt Squire. To be Surgeons-Apothecary to His Majesty's Household at Windsor: Mr. William Fairbank and Dr. William A. Ellison, M.V.O. To be Surgeon-Apothecary to His Majesty's Household at Sandringham: Sir Alan Reeve Manby, M.V.O. To be Surgeon-Apothecary to His Majesty's Household at Balmoral: Dr. Alexander Hendry. To be Honorary Physicians in Ordinary to His Majesty in Scotland: Sir Thomas Richard Fraser and Dr. David W. Finlay. To be Honorary Surgeons to His Majesty in Scotland: Dr. Alexander Ogston and Sir William Macewen, F.R.S. To be Honorary Surgeon-Oculist to His Majesty in Scotland: Mr. George Andreas Berry. To be Surgeon-Apothecary to His Majesty's Household at Holyrood Palace; Mr. William Black Alexander. To be Honorary Physicians in Ordinary to His Majesty in Ireland: Sir Francis Cruise and Dr. James Little. To be Honorary Surgeons to His Majesty in Ireland: Sir Charles Bent Ball and Sir Thomas Myles. To be Honorary Surgeon-Oculist to His Majesty in Ireland: Dr. Charles Edward Fitzgerald. Similar appointments have previously been held by many of these gentlemen either to the present King (when Prince of Wales) or to his late Majesty Edward VII., while some of the appointments are new.

AMERICAN PROCTOLOGIC SOCIETY.

THE Twelfth Annual Meeting of the American Proctologic Society was held at St. Louis, Mo., on June 6th and 7th. Dr. Dwight H. Murray (Syracuse, N.Y.) was President, and delivered an address on Undergraduate Proctology. Among the numerous papers read was a Brief Review of the History of the Society from its Organisation in 1899, by Dr. Lewis H. Adler, jun. (Philadelphia), secretary-treasurer. He said that a brief synopsis of the work of the society might impress the profession at large by what had been accomplished by proctology for the advancement of medicine. As the surgeon had rescued surgery from the barbers and the obstetrician the practice of midwifery from the ignorant and often grossly careless midwife, so the American proctologist, largely by means of this organisation, had advanced diseases of the rectum and sigmoid from the domain of quackery to a

recognised specialty, and had removed from the hands of the charlatan, to a great extent, a fertile field for playing upon the credulity and ignorance of the populace. This statement was supported by an account of the history of the society, including the titles and authors of the principal papers read at its annual meetings. Dr. Adler hopes that the publication of the transactions of the society will become a permanent feature, and those interested in the subject will find in them much useful information as to the work done and the progress made in this specialty.

MULTIPLE PNEUMOCOCCIC ABSCESSES OF THE LIVER.

IN the *Progrès Médical* of April 23rd Professor Henri Claude and M. M. Sourdel have reported a case of an unusual lesion due to pneumococcic infection—viz., multiple abscess of the liver. It has generally been supposed that in infectious hepatitis the infection takes place through the medium of the bile ducts (ascending infection), but the researches of Widal and his school have shown that the infection may commonly take place through the medium of the blood stream (descending infection). This has been found to occur in the hepatic complications of typhoid fever, pneumonia, and puerperal septicæmia, for the necropsies showed absence of angiocholitis. The case now reported is an example. A herdsman, aged 20 years and addicted to alcohol, was seized with severe pain in the side and had a rigor. After three days he was taken to hospital on Oct. 26th, 1909. The pain had almost disappeared and persisted only in the hepatic region. There was slight bulging in the right hypochondriac region. The whole abdominal wall was hard and tender on pressure and muscular resistance was marked. All the symptoms were most marked in the hepatic region. The liver was uniformly enlarged and extended four fingers' breadth below the ribs. On the lower lip was a group of herpetic vesicles. The tongue was moist and clean and the appetite was good. There was profuse diarrhœa without special characters. There was neither cough nor expectoration. At the base of the right lung slight dulness and "râles of congestion" were found. The pulse was 120 and the temperature was 104° F. The urine contained two grammes of albumin to the litre. Hepatic abscess was diagnosed. During the night the patient was restless, had constant rigors, and was covered with perspiration. On the following day there was bilious vomiting and the temperature had fallen to 99·3°. The urine was abundant and contained bile pigments, but there was no trace of jaundice. The abdomen was a little less painful and could be better examined. The liver was smooth, hard, and very large. The spleen was also enlarged. At the base of the right lung a small patch of crepitations and bronchial breathing were found. On the following day these signs disappeared. The temperature showed great oscillations—from 98° to 104°—and tended to be higher in the morning than in the evening. On the eighth day the acute pain had disappeared and the abdomen was again supple. Blood examination showed red corpuscles 4,500,000, and white 12,000, in which the percentages were as follows: polynuclears, 86·5; large mononuclears, 7·4; small mononuclears, 4·4; lymphocytes, 1·2; and eosinophiles, 0·4. The course of the fever, the leucocytosis, and, above all, the high percentage of polynuclears suggested suppuration. The signs in the hepatic region, in spite of the absence of jaundice, pointed to abscess, but in consequence of the difficulty of localisation an operation was not performed. The diarrhœa continued profuse; the stools were dark and fœtid and contained large quantities of bile. On Nov. 20th there was a hard swelling in the hepatic region, more diffuse than before. On the 24th there was slight jaundice and the urine became scanty and high-coloured. The jaundice increased, blood appeared in the stools, and death occurred on the 25th. The blood yielded a culture of the pneumococcus. At the necropsy the base of the right lung was found congested, and the mitral valve was thickened but showed no vegetations. The liver was much enlarged and adherent to the neighbouring viscera, but smooth and without trace of abscess on its surface. On section it was found deeply congested. At its centre was an abscess of the size of a small egg surrounded by a fibrous capsule and containing fœtid chocolate-coloured pus. Behind the abscess a large branch of the hepatic vein was thrombosed. The lower part of the liver was filled with small abscesses varying in size from a pea to a walnut. The gall-bladder was a little distended and contained a turbid fluid quite unlike bile. All the biliary passages were permeable and were not dilated. The splenic vein was thrombosed. The pus of the abscesses contained the pneumococcus and the colon bacillus. Evidently the primary pneumococcic lesion was at the base of the right lung. Infection of the liver seemed to have taken place through the blood, for there were no signs of inflammatory changes in portal spaces.

MEDICINE AND ATMOSPHERE.

THE atmospheric conditions of the last week have caused a general limpness and flaccidity in the community, a sense of oppression and languor due to the high saturation with moisture of the surrounding air. The rise of temperature in the shade has not been high, a degree or two above 70° F. at the utmost, but there was no getting away from the feeling of tiredness, and no advantage to be got from seeking shady places. The idea of a fire in the stoves of the sitting-rooms seemed absurd, and few people thought of meeting the weather thus. And yet, paradoxical as it may seem, artificial heat, under the conditions mentioned, is one of the best means of getting rid of the unpleasant feelings set up by these states of damp due to high saturation. Here we may take a lesson from the Swiss who employ dry heat with advantage when the air is damp though warm. The reasons for a fire—preferably of wood—are obvious; the air is dried, a current is made through the room and up the chimney, and the saturated atmosphere is made endurable through radiation. Those who have radiators in their houses will do well to have them set going to a moderate extent if the extreme mugginess returns, for it is really surprising what a feeling of coolness is thus produced. People smile at the Englishman's staple conversational topic, "the weather," but in truth its vagaries and changes have a great influence upon the energies and the movements of the population of these isles. The misery of those who retire to the dark seclusion of the cellar during periods of electric disturbance commands the sympathy of those more fortunately constituted persons who can brave the elements without anxiety. Many of the mental states of sensitive persons are directly due to atmospheric conditions which cannot be explained, although we may recognise them as actual existences. A certain amount of scientific investigation has been bestowed upon the alterations of pressure and the atmospheric changes generally which affect those who ascend to great heights or who go down to great depths, but work is still required in this direction on behalf of those who are contented to live on the plains, and yet have to endure painful feelings, rising at times to positive torture, from causes which are perhaps capable of modification by some simple physical remedies. Knowing the susceptibility of some people to certain atmospheric conditions, we merely wait for the weather to change, instead of trying to devise means by which

accommodation to the existing elements may be obtained, either by modifying the external conditions or by making the body harmonise better with its surroundings. During the hot weather of the first week in June of this year the way to combat languor was to light a fire; we are not at all sure that the public and the medical profession might not find between them other simple measures for dealing with physical ills, whose atmospheric origin is as yet not understood.

TEMPORARY RECOVERY IN STOKES-ADAMS DISEASE.

IN the *American Journal of the Medical Sciences* Dr. H. C. Earnshaw has reported a remarkable case of Stokes-Adams disease in which temporary recovery occurred. The patient was a well-developed man, aged 50 years, with reddish-grey hair, and florid complexion. He did not take alcohol; he used tobacco but not to excess. There was no history of syphilis. He had never been seriously ill. On Nov. 19th, 1908, he went to bed in his usual health. On getting up in the night he lost consciousness for about half a minute and found he had dropped on his knees. On arising he did not feel very weak and went back to bed. Twice more during the night in getting up he fell, but got back to bed. In the early morning he vomited. When seen on the morning of the 20th he was pale. At times he became very pale, the pupils contracted, the eyelids fluttered, the eyeballs rolled upwards, the facial muscles twitched, and a general convulsion followed with loss of consciousness. The pulse disappeared and the veins of the neck pulsated. Suddenly a faint flush appeared spread over the face, consciousness returned, and he looked round bewildered, but took up the conversation where it had stopped. Then the pallor gradually returned but not to such degree as before the attack. Occasionally he vomited, but there was no nausea. The pulse was 40 to 50, strong and regular, and after the convulsions increased slightly in rapidity. The cardiac dulness was normal; the sounds were strong; the pulmonic second sound was slightly accentuated; a faint systolic murmur was heard at the apex and was not transmitted. The urine contained albumin, epithelium, and an occasional granular cast. The attacks continued all day. Next morning the pulse had increased to 60; through the day an occasional convulsion followed by flushes occurred. On the following day the pulse was 70 and there was only a very occasional flush. Convalescence was then uninterrupted and by Nov. 27th he had completely recovered and the pulse was 80 to 90 and the urine normal. On Dec. 27th, while he was at the telephone, he fell, and a second attack followed and ran a similar course to the first one. On Dec. 29th the pulse was 60, but in the attacks there were pauses of 10 seconds. On Jan. 1st, 1909, the pulse-rate varied from 57 to 16 and during the pauses the pallor was extreme. Curiously, the lips retained their colour and the hands their warmth, though the lower limbs were cold. On Jan. 2nd the condition was alarming; one convulsion followed another, each lasting 20 seconds. The jugular veins were very prominent and pulsated more frequently than the radial pulse. On auscultation over the præcordium feeble auricular contractions could be heard between the ventricular beats and during the pauses. The ventricular sounds were weak, and the rate about 25, while the jugular pulsation varied from 80 to 100. Dr. Pepper of Philadelphia saw the patient in consultation, and took a tracing which showed complete heart-block. On Feb. 14th he was able to sit up in a chair, and on the 21st he went to the Johns Hopkins Hospital, where he had several attacks, under the care of Dr. Thayer. He returned home and a month later, on June 14th, another attack began. After six weeks the symptoms of heart-block disappeared, complete recovery followed, and the patient returned to business and was able to work as well as before. On Dec. 16th the pulse was 88, regular, full, and strong. A faint systolic murmur was heard at the apex. Subsequently an attack lasting several days occurred. Many drugs—nitro-glycerine, atropine, strychnine, morphine—and inhalation of oxygen were tried, but appeared to have no influence on the heart-block. It is difficult to understand how temporary recovery can take place from the lesions which give rise to heart-block—gumma, fibrosis, and fatty and calcareous degeneration. Some observers have suggested that as the union between the auricles and ventricles is very close muscular fibres outside the bundle may assume a compensatory function. It is conceivable that iodide might have some influence on a gummatous lesion, but in the present case syphilis seemed to be excluded. Dr. Earnshaw suggests that there was some sclerotic change in the nutrient vessels of the bundle which impaired its nutrition only when the local circulation was further interfered with by some temporary cause, possibly vaso-motor.

TERRA "INFIRMA."

THE instability of sea and air is proverbial; it seems the destiny of South-Western Italy to assert the same characteristic for the earth. In that region telluric tremors are so frequent that they are scarcely noticed by the natives; subterranean rumblings are as little heeded as the din of the street in great cities; it is only when the tremor becomes a shock and the rumbling has risen to a roar that the population realise that another earthquake has occurred. Fortunate are they if the result is not a cataclysm, engulfing tenements by the hundred and their inmates by the thousand, and adding another to the long list of such calamities as, beginning (historically) with that of A.D. 526, closes, for the time, with that of Dec. 28th, 1908! In a few seconds the whole physiognomy of a district or province may be changed, till the ordnance surveyor, recommencing his task, finds villages replaced by valleys and fields by lakes, till, in the words of a victim to one of these latter transformation-scenes, "I went to bed a farmer and woke a fisherman." South-Western Italy, indeed, may be justified in applying to herself the famous lines in which Juvenal describes the Rome of the first century:—

> "Nos urbem colimus tenui tibicine fultam
> Magna parte sui,"

only for "urbem" substituting "terram." In the sense that the sustaining power of the earth's crust may get unequal to the weight imposed upon it—a condition of things clearly proved as possible by Professor Palmieri of the Vesuvian Observatory in his treatise on the Ischian earthquake of 1883—she is warranted in looking with grave misgivings on the attempt to resuscitate Messina or Reggio Calabria on the old lines; nay, as a recent expert in the architecture required in earthquake-haunted regions remarked, even the running up of wooden huts on an extended scale has its dangers, if carried out with only a perfunctory testing of the "bearing power" of the soil. Necessary, perhaps, as a provisional means of supplying shelter the huts may ere long (for memory even in those regions is short) be replaced by houses, and a hamlet, or village, or a town itself, reappear, only to become a candidate for the doom of its predecessor. Soundings of the soil, deep-seated as well as extensive, must be taken before dwellings for a population of any magnitude can safely be erected; nay the geological expert must be called in to demonstrate that the area to be built over should be proof against seismic visitation, such, for example, as the valley of the Po and its immediate environs which, in the words of an authority on "*pathologie tellurique*," "sono in condizione privilegiata

rispetto ai terremoti" (are in a privileged state as regards earthquakes). The recent terrible cataclysm in the Basilicata, demanding, as it does, a relieving organisation only second to its Siculo-Calabrian predecessor, has sequelæ of its own of the gravest import for the Italian Government. "Why remain on a soil that, in the twinkling of an eye, may collapse and involve in ruin the labour of years, and in death the lives of an entire population?" Such are among the questions put to themselves by the agricultural families in South-Western Italy and answered by the immigration of thousands upon thousands annually to the New World. With every recurring earthquake the life-blood of the population undergoes depletion, and the young, the lusty, and the enterprising are lost to the country, leaving only the elderly and the weakly, not to say the decrepit, to add to the birth-rate. An alarming prospect this for a nation whose physique is not improving, as witness the rejection of nearly 40 per cent. of the youth drawn upon for military service! There are unreclaimed regions enough in the peninsula and the islands to accommodate most of these emigrants, if the reclamation works were only prosecuted with the intelligence and the energy required. That is the true "Italia Irredenta" for the present generation of Italians, not the outlying patches of Italian-speaking population on the Swiss or the Austrian slopes of the Alps or in the Istrian Triangle, or in the island of Malta. Concurrently with this work of redeeming from inertia, and restoring to healthy activity, the long derelict and deteriorated champaign or seaboard, epidemics will gradually disappear and a robust peasantry will earn a living wage, untempted to undergo the self banishment of voluntary emigration or to reinforce an alien and often an unsympathetic civilisation with elements which can ill be spared at home. If such a consummation should be brought about by the "telluric storms" and cataclysms of the last decade, Italy may come to look on these as blessing in disguise, regarding them as Nature's "oracular response" to the questions which have harassed her for centuries, a response which is really an appeal to all that is most enlightened, most masculine, and most patriotic in her organism.

THE FUNCTIONS OF THE PITUITARY BODY.

THE *Johns Hopkins Hospital Bulletin* for May, 1910, is wholly devoted to the description of a most interesting research carried out by Dr. S. J. Crowe, Dr. Harvey Cushing, and Dr. John Homans in the Hunterian Laboratory of Experimental Medicine at the Johns Hopkins University. The English investigator reads an article such as this with unstinted admiration of the thoroughness of the work, not unmixed with envy of the perfect conditions under which the task has been accomplished. The object of the work has been to determine whether the hypophysis cerebri in whole or in part is necessary to the maintenance of life; what symptoms occur during the period of survival; what symptoms are caused by partial removal; and, finally, which part of the gland is chiefly responsible for such symptoms as may follow wholesale destruction of the gland. The sum total of previous investigations has given forth an uncertain voice on every one of these points. Over 100 hypophysectomies were performed on dogs with all the aseptic care and circumstance that belong to human intracranial surgery. The method adopted has been Paulesco's, in which the base of the brain is approached by a temporal opening, a contralateral temporal opening being made to facilitate manipulation. The temporal lobe is lifted and an adequate access to the pituitary gland is thus assured. Certain operative complications occurred a few times, but the symptoms which followed total and partial hypophysectomy were not to be ascribed to injury of the brain, as is proved by respiratory and circulatory graphic records made during the operations, as well as by the absence of such symptoms when the gland was fragmented but not removed. The experimenters find that total removal of the gland leads to "apituitarism," which ends in death, in adult dogs after two or three days, in puppies after an average period of 11 days. The symptoms of apituitarism begin to be manifest about 24 hours after operation; the dogs become irritable and dull, the hind limbs move stiffly and unsteadily, the back is arched, the body temperature falls with the blood pressure, pulse, and respiration-rate, and life ends in coma. In young dogs the urinary output is increased, in older animals it is lessened. Similar symptoms follow removal of the anterior lobe alone, but if the posterior lobe alone be removed nothing happens. Partial ablation of the anterior lobe does not prove fatal, the smallest remnant proving adequate for maintenance of life; but after continued observations certain definite changes were noted which are of great interest in relation to those forms of infantilism which are associated with pituitary inadequacy in the human subject. The most constant phenomena were adiposity with dystrophy of the sexual organs in adults, and persistent sexual infantilism in animals operated on before adolescence. More or less often cutaneous changes were noted, also polyuria, glycosuria, low temperature, and psychic disturbances, together with a lowered resistance to infection and injury, the shock of which tended to precipitate the symptoms of apituitarism. After total removal it was found possible to prolong life by glandular transplantation or by injection of anterior lobe emulsion, while injection of boiled anterior lobe extract into animals in states of hypopituitarism excited a febrile response which the authors liken to the phenomena of anaphylaxis.

TUBERCULOSIS CONFERENCE.

A CONFERENCE under the auspices of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis will be held in Edinburgh from Friday, July 1st, to Tuesday, July 5th. Professor W. Osler will preside, and it is hoped that many of the authorities on the various aspects of tuberculosis, both in the United Kingdom, America, and the continent, will take part in the debates. On Saturday morning various addresses will be delivered to the teachers and scholars in the Edinburgh schools, while the afternoon will be occupied with the inauguration of the Royal Victoria Hospital Farm Colony at Springfield, Lasswade; a garden party will also be given by the committee of the Royal Victoria Hospital. On Sunday, at 3 P.M., a special service for university students and visitors will be held in the McEwan Hall, and an address will be delivered by Professor Osler. On Monday the Tuberculosis Conference will be held in the Rainy Hall from 10 A.M. to 12.30 and from 3 P.M. to 5.30. In the morning the subject for discussion will be the Avenues of Infection in Tuberculosis, while in the afternoon Preventive Measures and the Administrative Control of Tuberculosis will be considered. At 8 P.M. the eleventh annual meeting of the association will take place in the United Free Assembly Hall, when Lord Balfour of Burleigh, the chairman of the committee of the association, will preside. After the meeting the Provost, magistrates, and council of the city of Edinburgh will hold a reception for the delegates to the conference. On Tuesday the conference will conclude with discussions on the Incidence of Tuberculosis in Childhood, and on the Working-man in Relation to Tuberculosis. In connexion also with these meetings there will be a tuberculosis exhibition in the New College Buildings, which will be opened by the Countess of Aberdeen on July 1st.

This exhibition will be open daily to the general public, and special arrangements for conducting school classes round the exhibition will be made. We feel that this conference is of the highest importance, both as regards the education of public opinion on all matters relating to the prevention of tuberculosis and also in offering opportunity for the members of the medical profession to acquaint themselves with recent developments in the fight against this disease. Full particulars as to the arrangements for the conference can be obtained either from Dr. W. Leslie Lyall, 8, Murrayfield-gardens, Edinburgh, or from Dr. James Miller, 24, Queen-street, Edinburgh, the honorary secretaries.

VENTILATION OF TENTS IN THE TROPICS.

IT is now the fashion to talk of hygiene and sanitation in India; these subjects are popular in newspapers and magazines, but the resident in India experiences little change in ways of living, and as for comfort, people of every class and race there will go without it, if they can have more or less of luxury. The poorer classes, especially of the mixed races, who are mostly Christians of a sort, will suffer any privation in order to wear black clothing as a sign of mourning, but they will shut their windows at night for fear of the influence of the night air, and the poorest of Indians shut out the daylight from their houses by screens, although they begin to be familiar with all the precautions with regard to light and ventilation that are taken in hospitals. This is the season when the Indian official is on tour: the magistrate, the forest officer, the policeman, the engineer, pass five months of the year in camp, and many are the devices which these men employ to render life more agreeable and to facilitate the transport of their property. We have only to visit the great purveying firms in order to see the variety of goods prepared for the outfit of dwellers in tents. Furniture, cooking-gear, condensed foods, clothing, medicine chests, weapons, miniature libraries, are all there, but, strange to say, the tents remain pretty much what they were 30 or 40 years ago in the matter of ventilation. They are certainly more portable and more attractively built than before, but they are just as devoid as ever of provision for the circulation of air, for, above the entrance, which is from five to six feet high, there is no opening, and the air is stagnant even at the hottest period of the day, when there is no wind and circulation is most needed. It is hard to believe that so many educated men should have borne the discomfort of the touring tent for so many years without any attempt to find a remedy, but the evidence against them is overwhelming. They have doubtless all been taught that the air is less affected by the sun's direct ray than any other substance, and a simple test with the thermometer would show them that the air in the tent is hotter than the air outside, because it is inclosed and cannot circulate. Even at nightfall when the air without is cooling that in the tent cools much more slowly, being protected by the thick canvas. Part of the heat in a tent comes in with the light through the entrances, and these are covered by blinds that obstruct at least 60 per cent. of the passage, so that, unless a light breeze is blowing, a tent is always stuffy in hot weather. When the wall of a tent is erected around a leafy tree the best conditions of outdoor life are found. There is overhead a roof which arrests the sun's direct ray and affords perfect ventilation. Some approach to these conditions may be made in a tent by means of a slight alteration. One or more openings must be made as near the top of the tent as possible. They should be held in shape by strong open netting and protected by flaps from showers or the entrance of direct sunlight. These openings must be large, for they have to deal with a large volume of air. This ventilation will also assist the action of the wet screen that is used to cool and moisten the air at or near the entrance to a tent. When a tent is pitched in one place for several weeks at a time more complete arrangements may be made for ventilation, based on the varying absorption of heat by similar substances of different colours. The absorption by black is, for example, greater than white, and this fact may be utilised in a tent in the form of a circular canvas shaft or chimney dyed black and supported by a bamboo within which passing to the top engages with the sling of a hoop which distends the mouth of the shaft. The effect of this canvas shaft has not yet been measured, but a very thin iron shaft 22 inches square and 10 feet high exposed to the sun produced a current of 26,853 cubic feet of air per hour. The swinging punkah in a tent produces no ventilating current; it simply churns the air and prevents it from stagnating about the human body below it. It promotes, however, evaporation. The ventilating canvas tube continues to operate so long as any difference of temperature exists between the air in the tent and that outside of it, causing a complete and constant renewal of the atmosphere of the tent.

THE Board of Trade proposes to appoint a small Departmental Committee to advise as to what changes may be necessary in the system of sight tests for officers of the Mercantile Marine now in force. Evidence, we understand, is invited from interested persons.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on June 9th, Mr. BUTLIN, the President, being in the chair.

A letter was read from the Right Hon. Earl Howe, G.C.V.O., Lord Chamberlain to Queen Alexandra, conveying Her Majesty's thanks for the address of condolence of the President, Vice-Presidents, and Council of the College.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the recent examination 132 candidates presented themselves, of whom 36 were approved and 96 were rejected.

A report was received from the Court of Examiners respecting candidates found qualified for the diploma of Fellow, and in accordance with this report it was resolved to issue diplomas of Fellowship to 22 successful candidates.

In accordance with a report from the Nomination Committee it was resolved to reappoint all the present examiners.

A letter was read from Sir Henry Morris, Bart., reporting the proceedings of the General Medical Council at its recent general session. It was resolved that the letter be received and entered on the minutes, and the best thanks of the Council were given to Sir Henry Morris for his services as the representative of the College on the General Medical Council.

The PRESIDENT consulted the Council about sending a representative of the College to the Fifth International Congress of Obstetrics and Gynæcology to be held at St. Petersburg in September next, and Dr. Amand Routh was chosen as a representative of the College.

The PRESIDENT reported that a meeting of the Fellows would be held at the College on Thursday, July 7th, for the election of four Fellows into the Council of the College in the vacancies occasioned by the retirement in rotation of Mr. John Hammond Morgan, C.V.O., and Mr. Charles Barrett Lockwood, by the death of Mr. Henry Hugh Clutton, and by the resignation of Mr. George Arthur Wright.

A vote of thanks was accorded to Mr. Morgan, who does not seek re-election, and to Mr. Wright, for their services to the College.

The thanks of the Council were voted to the board of guardians of the parish of St. Marylebone for the gift of a number of old surgical instruments.

THE HEALTH OF THE BRITISH TROOPS IN INDIA.

Surgeon-General F. W. Trevor, principal medical officer to His Majesty's forces in India, has made, under date of May 10th, a most interesting report. In directing this report (which is given below) to the notice of the general officer commanding the various divisions Surgeon-General Trevor draws attention to the very favourable results obtained during the past year in improving the health of British troops in India, and the high appreciation of the good work which the Commander-in-Chief has expressed.

The accompanying tabular statement shows the position at a glance :—

Year.	Average strength.	Average number constantly sick.	Total invalids sent home.	Total deaths.	Ratio per 1000.									
					Admissions.	Deaths.	Constantly sick.	Enteric fever.		Dysentery.		Malaria.		Venereal.	
								Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
1902–1907 ...	70,495	3808·65	1968	741	879·3	10·51	54·02	16·8	3·38	13·9	0·48	174·1	0·29	161·5	0·15
1908	68,522	3139·10	1078	623	836·2	9·11	45·81	14·6	2·74	14·4	0·42	244·6	0·51	69·8	—

STATEMENT OF PRINCIPAL MEDICAL OFFICER.

It will be seen that this improvement has been progressive for some years and is doubtless due to a variety of causes, the more important being (1) an enhanced appreciation of the benefits accruing from anti-enteric inoculation on the part of both officers and men and increased efforts on the part of medical officers to carry out these inoculations and to detect mild or ambulant cases of enteric fever which formerly escaped detection; (2) the provision of steam disinfectors in various large garrisons and a greater attention to the details of prompt and adequate disinfection of bedding and clothing; (3) steady improvement in the sanitary condition of cantonments; (4) the greater interest taken by commanding officers and others in the sanitary condition of barracks and lines; and (5) an increased appreciation on the part of the men of the value of a rational mode of life, coupled with an intelligent conception of the principles of elementary hygiene.

It is only by a constant coöperation between commanding officers, cantonment magistrates, and medical officers that a high degree of sanitary efficiency can be maintained, and the results now brought to notice are highly encouraging for further efforts in the same direction.

2. At the present time nearly 45,000 men serving in India have been inoculated against enteric fever and the incidence of this disease among the troops serving in the command has fallen from 16·8 to 8·9 per 1000 of strength. It is desirable that continued effort be made to increase the numbers of men inoculated, and thereby secure a further reduction of this disease. To this end it is urged that no opportunity should be missed to impress upon officers and men the advantages to be obtained by submission to inoculation against enteric fever.

3. It is noticeable that the incidence of dysentery has been reduced. Our knowledge regarding the precise etiology and prevention of this disease is still imperfect and calls for further investigation and effort. It is desirable that in relation to this disease, enteric fever, and cholera the importance of constant and intelligent supervision of water-supplies, in respect of source, storage, and methods of distribution, be not overlooked.

4. The excessive incidence of malaria among troops is still a matter of anxiety. It is true there has been some improvement, but there are many points in connexion with its prevention which demand increased investigation and effort. The part played by mosquitoes in the dissemination of fevers should be persistently impressed upon the men and encouragement given to them to construct mosquito traps in the barrack-rooms. In addition to the ordinary measures for the extermination of these insects, more care needs to be taken to secure a higher standard of cleanliness in the barrack-rooms, as there is much reason to believe that neglected and dusty rooms are a fruitful source of increased prevalence of mosquitoes. As regards the use of mosquito nets, every opportunity should be taken to encourage their use, and where regimental or other funds are available enormous benefits may be anticipated if officers commanding be encouraged to provide these protections for their men, and induce men to use them, especially when sleeping out of doors. It is recognised that the financial difficulties in the way of providing nets for all the men are great; but material progress in this direction will be secured if nets are provided for and those actually infected with malarial parasites be induced to use them. To this end medical officers and those in charge of clinical laboratories should make every endeavour to detect "crescent" carriers, furnish nominal rolls to commanding officers of these virulently infected men with a view to their constantly sleeping under nets, and thereby reduce possibilities of dissemination of the parasites to others. Closely connected with this subject, I would remind you that recent research has shown that certain fevers of an indefinite type are conveyed by sand flies, and it is desirable that every effort be made to get rid of these insects.

5. I wish, further, to impress on all medical officers that the sanitary measures which have been so successful in the past should be amplified and carried out with greater vigour, if possible, during the ensuing season. In some cantonments the standard of efficiency is high, but in many others there is room for much more zeal and improvement. As the number of sick under treatment in hospitals has been greatly reduced, medical officers have more spare time at their disposal for work in barracks and lines and for research work. Activity in these directions is of the greatest importance in the prevention of disease, and it is only by frequent visits to barracks and the exercise of personal observation that the actual conditions under which the men live can be studied and defects or errors discovered and eradicated. It is particularly desirable that, in addition to ordinary or official inspections, the barracks, lines, and their surroundings be visited at unusual hours—that is, when inspection is not expected.

6. Unexpected visits to latrines, especially late in the evening, are of great importance. The use of the wet system of conservancy, as authorised, has resulted in the almost total absence of flies from latrines; this system should be strictly carried out. The pernicious influence of flies as disseminators of disease is well recognised, and every effort must be made to abolish these insects from cantonments. As regards incineration, it must be admitted to be a valuable means of disposing of rubbish, litter, &c., and has been used successfully for burning solid or semi-solid excreta, but evidence is wanting to show that it has disposed satisfactorily of liquid excreta in all places where tried and under all circumstances. Incineration must be regarded as a valuable asset to our means of defence in preventing disease, but at the present time it cannot be recommended as the *sole* means of conservancy in cantonments. In some cases where incineration has been carried on experimentally it has resulted in the production of a serious nuisance. It is desirable that constant attention be given to the practical working of incinerators, and surprise visits of inspection

made to observe the actual conditions of their working, in order that we may obtain the fullest information as to the precise rôle which they can play in our conservancy methods.

7. Soldiers' homes and institutes should be visited at the hours when the men use them, so that their sanitary condition may be noted. Special attention should be directed to the arrangements made for food storage, serving of food, the cleanliness of cooking utensils, and the whole sequence of events from purchase of food to the actual issue to the men. In a word, everything that concerns the personal hygiene of the soldier should be inquired into and advice given when necessary.

8. The condition of the men's bedding and clothing calls for careful scrutiny by medical officers. These articles need frequent exposure to the sun's rays, and it is suggested that much benefit would result if units systematically carry out this practice. The blankets in use should be distinctly marked either in worsted or by a metal tally with the man's name and number, so that some control be exercised over the use and issue of these articles, and that, in the case of infectious disease, there can be no doubt about the disinfection of the bedding. A mutual exchange of views between medical officers and commanding officers on this subject is desirable, and every effort made to place these issues under efficient sanitary control. Slackness in regard to this matter is one of the weak points in organised efforts to prevent disease.

9. Lastly, I would mention that during recent inspections it has been noticed that the eyesight of second- and third-class shots has not been frequently or efficiently tested. As bad shooting may be due to defective vision, capable of remedy by the provision of suitable glasses, it is desirable that the vision of these inefficient shots be systematically investigated and efforts made to remedy any disability.

MEDICINE AND THE LAW.

The Charity Commissioners and the Variation of Charitable Bequests.

A VERY important judgment of the Court of Appeal was delivered recently in a case in which the corporation of Wandsworth appealed from a decision of Mr. Justice Eve refusing to interfere with an order made by the Charity Commissioners. The order now set aside was made in connexion with the carrying out of the will of Mr. Benjamin Weir, who left two freehold houses and a large sum of money upon trust for the establishment of a dispensary, cottage hospital, convalescent home, or other medical charity for the benefit of the inhabitants of Streatham and its neighbourhood. The trustees were directed to use one of the houses as a hospital until the other, which was subject to restrictive covenants as to its user, could be converted into a hospital, when the two were to be used in conjunction. The covenants relating to the second house expired in 1907, the testator having died in 1902. Meanwhile, however, the trustees, with the sanction of an order from the Charity Commissioners, were about to carry into effect a scheme whereby the bulk of the money might be applied to enlarging and maintaining the Bolingbroke Hospital at Battersea, part of it only being devoted to a nursing home and dispensary, for which the two houses were to be used, and a sum of £5000 had in fact been paid to the Bolingbroke Hospital, which was to be renamed the Weir and Bolingbroke Hospital. The corporation of Wandsworth objected to this scheme on the ground that it did not carry out the wishes of the testator, which were obviously to benefit Streatham by the institution of a hospital within its boundaries under the name of the Weir Hospital. The Master of the Rolls, in delivering a considered judgment of the court reversing the decision of Mr. Justice Eve, laid down the principles governing the carrying out or variation of charitable bequests, after defining the jurisdiction of the Charity Commissioners as identical with that of the Court of Chancery and to be exercised upon the same principles. The first duty was to carry out the directions of the testator, provided that they were not either contrary to public policy or impossible of fulfilment. There was no evidence to show that a hospital could not be established as directed by the testator on such a scale that the whole of the money could properly be spent upon it. The trustees had to obey the terms of the will and had no right to say that in their opinion the hospital proposed would be of no use, or to bring about such a state of facts as would render it impossible to apply the whole income of the fund in maintaining it. The scheme sanctioned by the Charity Commissioners was not authorised. If they had gone wrong in a matter of detail only the court would not have interfered, but it was a question of principle, and it was the duty of the court to intervene because the rules of law governing such matters had not been complied with. The court expressed its surprise at the direction to pay £5000 to the governors of the Bolingbroke Hospital having been given before there was any scheme before the Commissioners. This decision of the Court of Appeal is likely not only to be accepted as a correct enunciation of the law upon the subject dealt with, but to be welcomed by those who desire that would-be testators should not be deterred from making charitable bequests. Such testators are very often guided by personal regard for a locality or for a particular class of beneficiaries, and it would be extremely likely to make them leave their money to other objects if they saw the charitable wishes of their neighbours frustrated at the will of their trustees or of the Charity Commissioners. It is quite possible that the Bolingbroke Hospital scheme might have been one of more marked public utility than the one which Mr. Weir devised, but this did not preclude him from having the right to dispose of his money as he chose, subject to the two conditions indicated by the Master of the Rolls.

An Action Against a Medical Man for the Loss of a Wife.

In the London Sheriff's Court recently a jury was asked to assess the damage suffered by a plaintiff owing to the loss of his wife, the defendant being a medical man, who had been called in to treat her, and owing to whose admitted negligence she had died. The liability of the defendant to compensate the plaintiff was not disputed by the former, and it was through his having allowed judgment to be entered against him that the case had been remitted from the High Court in order that a sheriff's jury might find the amount of compensation due. The deceased woman after having eaten some cocoanut felt unwell and consulted the defendant, who gave her a bottle of medicine. Immediately after she had taken some of it she was seized with severe pain, and the defendant, who was summoned to her house, endeavoured in vain to relieve her by means of a stomach pump. He also, before leaving the house, took the bottle of medicine referred to from a shelf, emptied part of its contents down a sink, and filled it up with water. Another medical man who was called in found the woman dead and diagnosed the case as one of strychnine poisoning. The defendant, when visited by the police (after the patient had died on the same night that she had been taken ill), expressed himself as prepared to certify the cause of death to have been ptomaine poisoning and collapse after three days' illness. In explanation to the other medical man he admitted having given strychnine, which had been found to be present in the bottle, and explained that he had done so because the deceased was suffering from a weak heart. After hearing evidence and a discussion as to the defendant's means, the Sheriff's jury assessed the damages at £200. In comment it must be said that defendant by his own admitted conduct in the case considerably increased the risk in which the death of his patient involved him. To tamper with the bottle which he gave her and to make inaccurate statements to the police were two of the most improper and dangerous things that he could have done. The matter appears, however, to have been concluded by the civil proceedings referred to above.

MEDICAL SCHOOL FOR INDIAN WOMEN.—The annual meeting of the North Indian School of Medicine for Native Christian Women at Ludhiana was held on June 7th in the Connaught Rooms, Freemasons' Hall, E.C., Colonel G. Gordon Young (a former Commissioner in the Punjab) presiding. Amongst the speakers were Dr. Edith M. Brown, the founder of the school; Miss L. M. Hill, the secretary; the Rev. Alexander Francis; and Dr. D. N. Chatterjee. The school was founded in 1894 and has now passed beyond the experimental stage. There is a well-equipped hospital attached to it, at which 24,483 out-patients and 1349 in-patients were treated last year. Here women are trained to work as practitioners and nurses amongst their own people, and, in addition to this, an important missionary work is carried on. The board requires two additional medical officers and two hospital sisters; funds also are urgently needed.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

The City of Manchester.—A report which relates to the health and in no small degree the social conditions of a school population of some 120,000 is a document of almost national importance, and we propose therefore to review it somewhat in detail.

Procedure as to Notifiable Infectious Diseases.

In the first place, the school work in Manchester is quite separate and distinct administratively from that of public health, and we may begin by considering the arrangements made for the co-relation of the public health service, the senior branch, with its very juvenile sister branch, the school medical service. These two services must clearly work in absolute harmony if maximum efficiency is to be maintained and if there is to be no overlapping and waste of effort. In dealing with cases of notifiable infectious diseases in the homes of school children the medical officer of health promptly notifies not only to the education authority but also to the schools immediately concerned, while conversely the school medical officers who investigate outbreaks of notifiable infectious disease in the schools duly notify to the medical officer of health the occurrence of missed cases and cases excluded from the schools on suspicion, and this officer follows up such cases in their homes. In cases of diphtheria or suspected diphtheria in the schools swabs are taken by the school medical officers and forwarded to the medical officer of health.

Procedure with Reference to Non-Notifiable Disease.

Here use is quite properly made of the school attendance officers who on discovering the existence of cases of measles, whooping-cough, and the like, notify them to the medical officer of health and deliver to the parents the exclusion-from-school forms which are supplied from the health officer, at the same time notifying the schools of such exclusion. This seems to us to be a very proper use to make of the school attendance officers, and it would be well if more were done in this direction elsewhere. The disinfection of the schools is carried out by the school authority as occasion arises, and it is of interest to note that the time of one assistant school medical officer is almost entirely taken up in dealing with infectious diseases.

The Instruction of Teachers in the Signs and Symptoms of Infectious Diseases.

The assistant school medical officers when visiting the schools in connexion with infectious diseases take the opportunity of educating the teachers in the manifestations of the several communicable maladies, and in addition to this object lesson it is the custom for them to deliver courses of lectures on hygiene to the pupil teachers. During 1909 some 228 teachers attended these lectures.

The Inspectorial Staff.

The school medical officer's staff consists, exclusive of himself, of four male and one female qualified assistants, together with six nurses. Each of the five assistants who carry out the routine inspectorial work is provided with a nurse, who takes charge of the instruments and who is present to assist in all the examinations. The sixth nurse is available for visiting the homes and for emergency work.

Attendance of Parents at the Examinations.

It is found by experience that there is considerable variation as regards the attendance of parents; sometimes as many as 90 per cent. attend, at others only 30 per cent. Their presence is, of course, found useful in the case of the younger children, but as regards those over 13 the necessary information can generally be procured from the child, although the mother's presence is welcome in connexion with any question of treatment which may arise.

The Following up of the Defective Children.

After the issue to the parent of the preliminary notice, which is on a white card and couched in plain non-technical terms, a variety of methods are adopted. The slight ailments are not further followed up, but, as regards more serious conditions, some are recorded on sheets and sent to the principal teacher who is asked to exercise his influence to obtain treatment and to report the result by a definite date, others are placed on various forms and entrusted to the nurse for visit and report. After the lapse of a reasonable time, if the parent has taken no proper steps, a second notice in the form of a green card is despatched to the parent either through the nurse or through the teacher, and failure to attend to this shortly results in the delivery of a third or warning notice on a red card, which is accompanied by a copy of the appropriate sections of the Children Act, 1908. When the child is verminous or filthy the legal 24 hours' notice is served by the attendance officer, and failure to act upon this is followed by the removal of the child from school and cleansing at the municipal cleansing station, which, by the way, was only available towards the end of 1909. As a matter of fact, however, the bulk of the cases are dealt with by the parents on the receipt of the notice. Cases other than these are asked to attend at the education offices where the parents are interviewed by the school medical officer, when the consequences of further neglect are explained, as they are summoned before the rota dealing with the school at which the child attends and official prosecution may result. As an example of what the rota is able to bring about, it is recorded that of 81 cases brought before it 60 received attention, 4 had left the district, and 17 are being followed up. Each of the steps above referred to is followed by a visit from a medical man or nurse, so as to ensure that no case receives an unnecessary notice, and in consequence of the several steps taken it has been found that of all the cases actually followed up somewhere about 94 per cent. have received treatment.

Methods and Institutions Available for Treatment of Defects.

No treatment is undertaken by the education authority, the parents or guardians being advised to obtain treatment either through a medical practitioner or at one or other of the hospitals. There are in Manchester many institutions at which relief can be obtained, and amongst them are two eye hospitals, a dental hospital, a hospital for diseases of the throat and nose, a hospital for diseases of the throat and chest, a hospital for the treatment of skin diseases, two general hospitals or infirmaries, a general children's hospital, and two hospitals for women and children, as well as a number of dispensaries at which treatment can be procured for an almost nominal fee. In addition there are available numerous charitable organisations as well as the Poor-law medical service. On the whole Dr. A. Brown Ritchie, the school medical officer, is of opinion that except as regards dental work Manchester is in the happy position of possessing ample provision for the treatment of the defects discovered. It must, however, be pointed out that although medical treatment is not provided by the education authority, spectacles are furnished for children who have been duly examined and for whom glasses have been prescribed, and during 1909 there were 318 pairs supplied. But these glasses are only provided to those who apply for assistance, in which circumstances the parents pay, if they can, the whole or part of the cost; otherwise they are provided free. The total cost of the spectacles supplied during the year was £23 1*s.* 9*d.*, and the average cost was 1*s.* 5·4*d.* per pair.

The Provision of Meals for Necessitous Children.

It is difficult to separate this provision from treatment, although it is not, of course, officially so regarded. As a general rule the parents take the initiative by an application to have their children fed, and after an investigation into the home circumstances the applications are dealt with according to the average income per head in the home after deduction of the weekly rent. Altogether there were 1783 applications for free meals made during 1909, and of this number 1492 were fed.

Method adopted for dealing with Physically and Mentally Defective Children.

The blind and deaf, as well as the mentally and physically unfit and the epileptic, are examined by the school medical officer and are referred respectively to residential or day schools. The physically defective are sent to a residential school for cripples; the mentally defective are either sent to one of the four special schools carried on within the area, or to the Lancashire and Cheshire homes at Sandelbridge, or they are excluded from the schools as being of too low a grade for either of the above. Epileptic children are accommodated at a residential colony.

The Incidence of Infectious Disease Prior to, and During, School Life.

Some interesting facts have been elicited by one of the assistant school medical officers as to previous incidence of certain infectious diseases, a study having been made of 3000 children, 1500 "fives," and 1500 "thirteens," at both of which ages the inspection has embraced the previous history. Amongst the children at 5 years of age it was found that 70·3 per cent. had already had measles, 43·7 per cent. whooping-cough, and 8 per cent. scarlet fever, facts which are of considerable importance in relation to the influence which schools may be regarded as exercising in the spread of the diseases in question. With respect to scarlet fever alone it was found that the percentage which had been infected at 13 years of age was 20 per cent., as compared with 8 per cent. at 5, as stated above. The figures for Manchester are then taken for the years 1894–1908, inclusive, and it is found that 10,226 cases of scarlet fever, with a fatality rate of 10·7 per cent., occurred amongst children under 5, while for children aged between 5 and 15 there were 19,752 cases, with a fatality rate of 2·5 per cent.—i.e., the average attack-rate upon children below 5 is a little above 2000 per annum, while upon the children from 5 to 15 just below 2000. It is stated that the maximum increase in the number of cases is during the third year of life—i.e., before the commencement of school life. The *rate* of increase then rapidly decreases until the greatest number occurs in the sixth year, when the annual number then begins to steadily decrease. It is contended that these figures fail to support the view that school life increases the frequency of infection, since the aggregation being constant throughout the ten years of schooling the rate of infection markedly decreases after the second year of school attendance. It is, no doubt, difficult to ascertain precisely what amount of infective disease is due to school life, but it does not, of course, follow that because the young children infected were not attending school their scarlet fever was entirely unconnected with the school. So many, perhaps the majority, of the actual cases of scarlet fever escape recognition that in a family some members of whom attend school and others do not, it is difficult to ascertain the source of the disease. In the view of the medical officer who has made these interesting observations, a joint investigation by the medical officer of health and the school medical officer will show that a very large proportion of the cases have had "no direct connexion with the school at all, any more than the fact that they have all been drinking tea proves that the tea is the cause of their illness." This seems to us somewhat to strain the real position, since aggregation is recognised as being a potent cause of infection, whereas there is no evidence whatever that the disease can possibly be spread by tea. The major factor in the spread of scarlet fever may possibly be age proclivity, but even if this be so, school influence may be a not unimportant factor. The fact that during 1909 out of 2259 cases of scarlet fever which occurred only 19 were actually discovered by the medical officers in the schools may in itself suggest how many cases may be overlooked. It would be an instructive piece of work if an inquiry were made in Manchester on the same lines as was made by Sir Shirley Murphy for London into the effect of the long vacation upon the behaviour of such diseases as scarlet fever and diphtheria.

Physical Condition and Mental Progress.

The relation of success in life to physical fitness is well brought out by an investigation into the condition of children of 13 years of age, at which age a child should normally be in Standard VII. The investigation went to show that the average 13 years old child who had not then got beyond Standard V. was shorter and lighter than his rival who had reached the higher standards.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8474 births and 3718 deaths were registered during the week ending June 11th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 13·8 to 11·8 per 1000, further declined to 11·4 in the week under notice, and was considerably lower than in any previous week of this year. During the first ten weeks of the current quarter the annual death-rate in these towns averaged only 13·2 per 1000, and in London during the same period it was so low as 12·7. The lowest recorded annual rates of mortality during last week in these 77 towns were 2·5 in Reading, 4·3 in King's Norton, 4·8 in Hornsey, and 5·7 in East Ham; the rates in the other of the large towns ranged upwards, however, to 17·2 in Stoke-on-Trent, 17·5 in Preston, 18·0 in Liverpool, and 21·6 in Merthyr Tydfil. In London the recorded death-rate last week was so low as 10·5 per 1000. The 3718 deaths registered last week in the 77 towns showed a further decline of 118 from the low numbers in recent weeks, and included 381 which were referred to the principal epidemic diseases, against 425 and 369 in the two preceding weeks; of these 381 deaths, 149 resulted from measles, 120 from whooping-cough, 49 from diarrhœa, 26 from diphtheria, 20 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·2 per 1000, against 1·3 and 1·1 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Leicester, Plymouth, Norwich, Burnley, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·9 in Liverpool and in Oldham, 3·0 in Blackburn, 3·2 in Stoke-on-Trent, and 3·3 in Barrow-in-Furness. The fatal cases of measles in the 77 towns, which had been 157 and 141 in the two preceding weeks, rose again to 149 last week, and caused annual rates equal to 1·9 in Burton-on-Trent, 2·0 in Merthyr Tydfil, 2·3 in Blackburn, and 2·5 in Barrow-in-Furness. The 120 deaths from whooping-cough showed a further slight decline from the numbers in recent weeks; the highest annual rates from this disease last week were 1·4 in Grimsby and in Wallasey, 1·5 in Bootle, and 1·6 in St. Helens. The deaths attributed to diarrhœa, which had been 49 and 46 in the two previous weeks, rose again last week to 49. The 26 fatal cases of diphtheria, were within one of the number in the previous week, and included 3 in Stoke-on-Trent, and 2 each in Birmingham, Liverpool, Preston, and Bradford. Of the 20 deaths from scarlet fever, 4 occurred in Stoke-on-Trent, and 2 both in Bolton and in Sheffield. The deaths referred to enteric fever in the 77 towns, which had been 17 and 10 in the two preceding weeks, were again 17 last week, and included 3 in London and 2 in Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital further declined last week to 1401, and were fewer than at any time during the last six months; 181 new cases of this disease were admitted to these hospitals during last week, against 174 and 203 in the two preceding weeks. Of the 983 deaths registered in London during last week only 137 were referred to pneumonia and other diseases of the respiratory system, and were 29 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 29, or 0·8 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in London, Leeds, Sheffield, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Stoke-on-Trent, Leicester, and in 50 other smaller towns; the 29 uncertified causes of death in the 77 towns last week included 4 in Birmingham, 3 in Liverpool and in Preston, and 2 each in Manchester, Burnley, Gateshead, and Burton-on-Trent.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 970 births and 514 deaths were registered during the week ending June 11th. The annual rate of mortality in these towns, which had been equal to 14·0 and 14·3 per 1000 in the two preceding weeks, was 14·2 in the week under notice. During the first ten weeks of the current quarter the death-rate in these towns averaged 15·9 per 1000, and exceeded by 2·7 the mean rate during the same period in the 77 largest English towns. The annual death-rates last week in these eight Scotch towns ranged from 9·0 and 10·6 in Aberdeen and in Paisley,

to 19·3 in Dundee and 19·6 in Perth. The 514 deaths from all causes in the eight towns during last week showed a decline of 3 from the number in the previous week, and included 59 which were referred to the principal epidemic diseases, against numbers declining from 87 to 50 in the five preceding weeks; of these 59 deaths, 22 resulted from diarrhœa, 13 from measles, 9 from whooping-cough, and 5 each from scarlet fever, diphtheria, and "fever," but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·6 per 1000, against 1·2 in the 76 English towns, and was 4·2 in Perth and 4·3 in Dundee. The 22 deaths attributed to diarrhœa last week in the eight Scotch towns showed an increase of 7 upon the number in the previous week, and included 15 in Glasgow, 3 in Dundee, and 2 in Perth. The fatal cases of measles in the eight towns, which had declined from 52 to 20 in the five preceding weeks, further fell last week to 13, of which 7 occurred in Dundee and 5 in Glasgow. The 9 fatal cases of whooping-cough showed a further slight increase upon recent weekly numbers, and included 5 in Glasgow and 3 in Dundee. All the 5 deaths from scarlet fever, and 4 of the 5 fatal cases of diphtheria, were returned in Glasgow. The 5 deaths referred to "fever" showed an increase upon recent weekly numbers, and included 4 fatal cases of typhus registered in Leith. The deaths referred to diseases of the respiratory system in the eight towns, which had been 98, 80, and 82 in the three preceding weeks, further declined last week to 67, and were 13 below the number returned in the corresponding week of last year. The causes of 17, or 3·3 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 691 births and 393 deaths were registered during the week ending June 11th. The mean annual rate of mortality in these towns, which had been equal to 21·1 and 18·0 per 1000 in the two preceding weeks, further declined to 17·8 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these Irish towns averaged 20·9 per 1000, whereas the mean rate during the same period did not exceed 13·2 in the 77 largest English towns and 15·9 in the eight principal Scotch towns. The annual death-rate during last week was equal to 16·4 in Dublin, 19·7 in Belfast, 19·9 in Cork, 9·6 in Londonderry, 16·4 in Limerick, and 29·2 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 16·7 per 1000. The 393 deaths from all causes in the 22 town districts last week showed a further slight decline from the numbers in recent weeks, and included 55 which were referred to the principal epidemic diseases, against 59, 50, and 58 in the three preceding weeks; these 55 deaths in the Irish towns were equal to an annual rate of 2·6 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·2, and in the eight Scotch towns 1·6 per 1000. The 55 deaths from these epidemic diseases in the Irish towns last week included 40 from measles, 7 from diarrhœa, 6 from whooping-cough, and 1 each from diphtheria and enteric fever, but not one either from scarlet fever or small-pox. The fatal cases of measles in the 22 town districts, which had been 33 and 39 in the two preceding weeks, further rose last week to 40, of which 38 occurred in Belfast. The 7 deaths attributed to diarrhœa showed a slight increase, and included 3 in Dublin. Of the 6 fatal cases of whooping-cough, 5 occurred in Belfast; and the death each from diphtheria and enteric fever were also there recorded. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 90 and 75 in the two preceding weeks, were 78 in the week under notice. The causes of 17, or 4·3 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent., while in the eight principal Scotch towns it was equal to 3·3 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet (dated June 9th, 1910):—Charles Arthur Gayer Phipps, Stanley Samuel Howard Shannon, and Reginald Lewis Jones.

The following appointments are notified:—Fleet-Surgeons: P. H. Boyden to the *Tamar*, additional, for Wei-Hai-Wei Sick Quarters, and J. F. Hall to the *Fisgard*. Staff-Surgeons: T. B. Shaw to the *Victory*, additional, for temporary service at Haslar Hospital; and A. X. Lavertine to the *Sutlej*. Surgeons: C. G. Sprague to the *Inflexible* and T. C. Patterson to the *Pembroke*, additional, lent Chatham Hospital, temporarily.

SUBMARINES AND EYESIGHT.

In the House of Commons on June 14th, in reply to a question by Mr. Gretton (on behalf of Lord C. Beresford), Mr. McKenna said there was no evidence that officers and men had their eye-sight affected in consequence of serving in submarines.

ROYAL ARMY MEDICAL CORPS.

Colonel S. C. B. Robinson, principal medical officer of the Fifth (Mhow) Division, Southern Army, India, has been granted four months' leave. Colonel E. Butt, principal medical officer of the Presidency and Assam Brigades, has joined at Darjeeling from Calcutta. Lieutenant-Colonel H. W. Austin has been transferred from the Southern to the Aldershot Command. Lieutenant-Colonel P. C. H. Gordon, on return from a tour of foreign service in Burma, has been appointed to command the military hospital at Bulford, Salisbury Plain. Lieutenant-Colonel S. Townsend, from Dover, has been posted to Canterbury. Major J. R. M. McMunn, on return from South Africa, has been posted to the Southern Command and appointed Registrar and Adjutant to the Royal Victoria Hospital at Netley. Major J. C. Jameson has arrived home from Egypt on leave. Major G. T. K. Maurice, from Muttra, has been transferred to the home establishment and posted to Bulford Camp, Salisbury Plain. Major A. E. Milner has joined the Southern Command from London District. Major B. H. Scott, from Edinburgh, has been appointed Deputy Assistant Director-General at the War Office, vice Major H. J. M. Buist, D.S.O., whose tenure of appointment has expired. Major J. D. Alexander has arrived home on leave from India. Captain H. Gibson, from Cosham, has joined at Poona. Captain E. W. Powell and Captain J. S. Dunn have arrived home from India and Captain E. Gibbon from Egypt on leave. Captain F. J. C. Heffernan has been transferred from Dinapore to Lucknow. Captain D. E. Curme, from Aldershot, has been posted to Ewshot. Captain N. J. C. Rutherford, from Canterbury, has joined at Harrismith. Captain E. E. Ellery has been appointed to Cairo. Captain R. J. C. Thompson has been seconded for service with the Egyptian Army. Captain H. H. Norman and Captain H. O. M. Beadnell have arrived home on leave from India. Captain C. T. Edmunds has embarked for India. Lieutenant S. Field, on completion of a tour of special service in Somaliland, has been posted to Chatham. Lieutenant F. H. M. Chapman has been transferred from Lebong to Darjeeling for duty at the station hospital during the summer months. Lieutenant J. C. L. Hingston, from Edinburgh, has joined at Cosham. Lieutenant M. J. Williamson, from Bulford, has been appointed to the medical charge of the artillery camp at Larkhill, Salisbury Plain.

DEATHS IN THE SERVICES.

Surgeon-Major-General John George Faught, A.M.S. (retired), Honorary Surgeon to the King, at Southsea on June 12th, in his seventy-eighth year. He entered the service as assistant surgeon in 1855, became surgeon in 1867, surgeon-major in 1873, and surgeon-major-general in 1890, and retired in 1892. He was employed as sanitary officer at Cape Coast Castle during the Ashanti war in 1874 (medal), served in the Afghan war, 1878–80 (medal), in the Egyptian war, 1882 (medal and Khedive's star), and with the Bechuanaland expedition under Sir Charles Warren, 1884–85, as principal medical officer. He was also principal medical officer in the operations in Zululand in 1888.

Lieutenant-Colonel Hubert Rothwell Greene, R.A.M.C.

(retired), on June 4th, at Dunstable, in his seventieth year. He entered the service as assistant surgeon in 1863, becoming surgeon in 1873 and surgeon-major in 1876. He retired with the honorary rank of surgeon-lieutenant-colonel in 1886. He held at one time the post of First English Director of Egyptian Sanitary Administration and served in the Afghan War of 1878–80 (medal), in the Egyptian Expedition of 1884 (mentioned in despatches), and in the Wady Halfa Hospital during the Soudan Expedition of 1884–85.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—To be Colonel: Lieutenant-Colonel Courtenay Clarke Manifold (dated March 29th, 1910). Lieutenant to be Captain: Harold Mundee Inman (dated Feb. 2nd, 1910).

Lieutenant-Colonel W. D. Sutherland, Civil Surgeon of Sangor, Central Provinces, has been appointed to the medical charge of Damoh District. Lieutenant-Colonel J. W. Rodgers has been appointed to officiate as Principal Medical Officer of the Fifth (Mhow) Division, Southern Army, India, during the absence on leave of Colonel S. C. B. Robinson. Lieutenant-Colonel P. D. Paul has been permitted to retire from the service from May 17th. Lieutenant-Colonel F. C. Clarkson, Bombay, has arrived home on leave. Major P. K. Chitale, Civil Surgeon of Damoh, Central Provinces, has been granted three months' privilege leave. Major J. G. P. Murray, Bombay, has had his leave extended. Captain H. W. Pierpoint has been appointed to officiate as Civil Surgeon of the Chanda District. Captain T. H. Gloster and Captain E. C. C. Maunsell have arrived home on leave from India. Captain J. MacG. Skinner has been posted for duty under the Home Department of the Government of India to the Madras Presidency, and Captain G. F. Morison to Eastern Bengal and Assam. Captain C. A. Sprawson has been appointed for duty in the United Provinces. Captain N. S. Wells, Officiating Civil Surgeon of Budaun, United Provinces, has been granted special leave for six months out of India. Captain W. J. Frazer has been posted temporarily to the Central Provinces for duty. Captain E. C. Taylor has been appointed Civil Surgeon of Miranshah. Captain J. Anderson has arrived home on leave. Captain G. C. L. Kerans has been appointed Specialist in Ophthalmology to the Eighth (Lucknow) Division. Captain W. J. Collison has had his leave extended by four months on medical certificate. Lieutenant A. M. Dukes, in charge of the Brigade Laboratory at Shillong, has been appointed a Specialist in the Prevention of Disease.

INDIAN MEDICAL SERVICE EXAMINATION.

An examination for not less than 15 commissions in the Indian Medical Service will be held in London on July 25th and following days. Full particulars can be obtained on application to the Military Secretary, India Office, S.W.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Highland Field Ambulance: The undermentioned officers to be Majors (dated April 1st, 1908):—Captain Alexander Ogston and Captain Thomas Fraser.

2nd Highland Field Ambulance: Captain Francis Kelly to be Major (dated April 1st, 1908).

3rd Highland Field Ambulance: Captain William E. Foggie to be Major (dated April 1st, 1908).

1st Scottish General Hospital: Major Arthur Hugh Lister, from 2nd Highland Field Ambulance, Royal Army Medical Corps, to be Major, whose services will be available on mobilisation (dated Dec. 1st, 1909). Major Arthur H. Lister to be Lieutenant-Colonel (dated May 22nd, 1910).

For attachment to Units other than Medical Units.—Lieutenant John A. Gibb to be Captain (dated Dec. 2nd, 1909). Richard Vernon Favell to be Lieutenant (dated April 15th, 1910).

Attached to Units other than Medical Units.—Lieutenant John W. T. Walker to be Captain (dated April 1st, 1908). Lieutenant Robert V. G. Monckton resigns his commission (dated May 9th, 1910).

THE SANITARY SERVICE OF THE TERRITORIAL FORCE.

General Sir Harry N. D. Prendergast, V.C., presided at the Imperial Institute on June 8th over a meeting convened for the purpose of stimulating interest in the sanitary service of the Territorial Force. Lieutenant-Colonel C. H. Melville, R.A.M.C., professor of hygiene at the Royal Army Medical College, said that, unlike the soldiers of the Territorial Force, the sanitary department would be allowed no breathing interval between the call for service and the first experience of war. From the first moment that the army was mobilised their work would begin. If they had not learnt their work in peace time they would have to learn it during the period of waiting for the enemy, and the price of that lesson would be so many Territorial privates in hospital and so many under the sod, therefore so many less ready to meet an invader. It was therefore their duty in peace time to study the conditions that they would have to face in war.

TERRITORIAL NURSING.

On June 11th, at the Japan-British Exhibition, Lady Helen Munro Ferguson, in the absence of the Duchess of Montrose, presided over a meeting of the Women's Congress, at which a discussion took place on the subject of Red Cross and General Nursing. Miss Haldane said that it was of little advantage to have 300,000 or a much greater number of men to defend our shores if we were not prepared to care for them in sickness. Unless on mobilisation an army was constantly being relieved of its sick and wounded, advance was made almost impossible. 23 hospitals, each having 520 beds, had been organised all over the country from Aberdeen to Brighton. These hospitals were not buildings specially erected, but public buildings which were ear-marked, so to speak, as hospitals. The *personnel* was definitely fixed upon. The Territorial Nursing Service was managed by a Matron-in-Chief at headquarters and principal matrons at each centre, along with an advisory council, which met in the War Office, or local committees. The Voluntary Aid Detachments were springing up everywhere, with their commandants, medical and other officers, all acting under a county director. The whole work, though done for the War Office, was entirely undertaken by the British Red Cross Society, though the St. John and St. Andrew's Ambulance Societies had the first teaching work imposed upon them. The women were not only certificated in first-aid, but also in nursing, cooking, disinfecting wards, and so forth. Field days were being arranged, and competitions between rival detachments were in prospect. It was a peace movement, and all these preparations were useful in civil life. Miss McCaul said that one reason why the Japanese Red Cross Society was so far in advance of other Red Cross societies was that it had been made to take a part in the daily life of the country.

RED CROSS SOCIETY.

The Marchioness of Winchester presided at the first annual meeting of the Hampshire county branch of the Red Cross Society which was held at the Castle, Winchester, on June 4th. Owing to the undesirability of asking for separate subscriptions for both the St. John Ambulance Association and the Red Cross Society, it was suggested that one subscription should be made for the two institutions, but the suggestion was not adopted. The Marquis of Winchester said that it might be possible to obtain some system of obtaining St. John certificates which could be recognised by the War Office and which would fulfil the necessary requirements of the Red Cross Association. Mr. Lockhart E. W. Stephens suggested that the War Office should detail some officers of the Royal Army Medical Corps to take one or more divisions for the purpose of informing the commandants exactly what to do when mobilisation takes place. He thought it was the duty of a military medical officer rather than that of a civilian practitioner, and it was not fair to ask the latter to learn the Royal Army Medical Corps manual in addition to his private work.

BALNEOLOGY AT BUXTON.—A meeting of the members of the Balneological and Climatological Section of the Royal Society of Medicine took place recently at Buxton under the presidency of Dr. Leonard Williams. The Fellows and guests, who were received by the president and members of the Buxton Medical Society, visited the Devonshire Hospital, where some interesting cases, among others, of rheumatic arthritis and gout were shown. They then proceeded to inspect the Buxton Baths. In the evening a dinner, followed by a smoking concert, was held at the Palace Hotel, and on Sunday the Fellows and guests visited places of interest in the vicinity of Buxton. From every point of view the meeting was a successful one.

Correspondence.

"Audi alteram partem."

THE WORK OF DR. CARLOS J. FINLAY IN RESPECT OF INSECT-BORNE DISEASE.

To the Editor of THE LANCET.

SIR,—I was very much surprised on reading Professor Osler's address before the London School of Tropical Medicine to find that Dr. Carlos J. Finlay's name had been entirely left out of all consideration in the discussion of the new discoveries concerning the transmission of diseases by blood-sucking insects.

There has been a tendency in the United States to slight the influence of Dr. Finlay's work in the foundation of these new doctrines. Dr. Finlay, with his rather pugnacious logic, of Scotch origin, was the first to combat the old prejudices and to stem the tide of ridicule and argument that was brought in their support. He also participates, on equal terms, I think, in the great glory of the discovery, thereby making it, in that much, less of an exclusive American triumph. For the same reason it has been also the tendency to forget at times the name of Dr. Agramonte, a Cuban, who was a member of the Commission of Officers of the American Army, who so brilliantly made the final and conclusive demonstrations in the matter of yellow fever.

For my part I do not hesitate in declaring that the founders of the doctrine upon which the great series of triumphs in tropical medicine is based are Dr. Manson and Dr. Finlay, a statement which does not detract in the least from the equal merit of the great experimenters who followed them, Smith and Kilbourne, Ross, Grassi, the American Army Commissioners, Koch, and other original investigators and discoverers. Back of these there is absolutely nothing. There is no difference whatever between the popular credence of the negroes of Africa and the Italian peasants, who believed that fevers were produced by the bites of mosquitoes, and the writings of Not, Beaupertuy, and King. He who follows these authors chronologically may imagine from the outward show of scientific apparel that he is progressing in a process of evolution of a great doctrine, but he soon finds that he is following a vicious circle that brings him back to the negroes of Africa, and to nothing practical. It may appear for a moment that Dr. Beaupertuy strikes out of the circle, and that he brings forward, a fact, when he speaks of the mosquito *à pattes rayés de blanc*, the *zancudo bobo*. This mention, frequently repeated, is made to serve as proof that Dr. Beaupertuy had fixed accurately upon the actual transmitter of yellow fever, the *Stegomyia calopus*, characterised by white ringed joints in the six legs. But this is not true. In the first place, the *zancudo bobo* is not the *stegomyia*. *Bobo* means silly, dull, and the *stegomyia* is one of the most alert of mosquitoes. The term *mosquito bobo* is applied by us to the *Culex sollicitans*, also a striped mosquito that breeds along the seashore in salt and brackish water, that invades human habitations in enormous swarms, and that might have fitted into Beaupertuy's theory of the origin of yellow fever in decomposing swamp plants from whence, he believed, the infection was brought by mosquitoes to man. This insect is called *bobo* because it is the dullest of our mosquitoes, being easily killed by gentle application of the hand when the insect is in the act of feeding. To kill the *stegomyia* or the *pipiens*, under the same circumstances you have to give a quick slap. The twisting of Dr. Beaupertuy's statement into service consists in ignoring that he singles out this particular mosquito precisely to say that it is *not* the producer of yellow and malarial fevers. "*Elle est la plus commune et sa piqûre est inoffensive comparativement à celle des autres espèces.*"

I wish to leave on record what Dr. Finlay said and did precisely at the time that the American Commissioners were about to commence their epoch-making investigation. The African negroes, who designate the mosquito by the same name that they apply to their fevers, the Italian peasants, and Drs. Not, Beaupertuy, and King were equally removed from the possibility of doing what Dr. Finlay did. This extraordinary man had studied very carefully the habits and geographical distribution of the *stegomyia*, or *culex mosquito*, Desv., as it was then called. He had studied the anatomy of the insect, he had determined its manner of feeding and breeding, he had studied its behaviour under varying influences of temperature and atmospheric pressure, and upon these facts, discovered and analysed by him, he explained with mathematical precision, as we do now, all the phenomena of the epidemiology of yellow fever.

Dr. Finlay met the American Commission with this mosquito in his hands. During 20 years he had been breeding it in test-tubes and jars, in the manner which was afterwards employed by Ross, and Grassi and others, and had been subjecting it to a series of most ingenious experiments, all carefully recorded. In presenting his mosquitoes he said:—

> If you take this mosquito and apply it to a yellow fever patient and allow it to feed on his blood you will have an infected insect, capable of producing immunity (here he was mistaken) if you apply it within two or three days after the bite, to a well man; and capable of producing a severe form of the disease if you apply it later.

This statement he had made in writing in 1891, as follows:—

> By the term "contaminated mosquitoes" I understand such as have stung a yellow fever patient during the first six days of the disease, and it is my belief that whereas one or two stings from mosquitoes recently contaminated may either occasion in susceptible persons a mild attack, or simply confer immunity without any pathogenic manifestations, a severe attack would result from a greater number of such stings, and the same might also occur in consequence of a single sting from a mosquito that should have been fed exclusively on sweet juices during several days or weeks, after its contamination, before it is allowed to sting another non-immune subject. (See *Revista de Medicina Tropical*, Havana, 1903, vol. iv., p. 136).

Now, these insects, *actually* received from the hands of Dr. Finlay, were *the ones* employed by the American Commission to bring about the demonstration of the new doctrine. This presentation of his mosquitoes to the United States Army Commission was made in 1900. In 1899 he had written the following statements, which are taken from his address "On the Methods of Stamping Out Yellow Fever, suggested since 1899," read before the Conference of State and Provincial Boards of Health of North America in October, 1902:—

> I expressed my ideas on these points in a paper which I contributed to the World's Congress Auxiliary of Chicago in 1893, "On Etiological Factors Concerned in the Propagation of Yellow Fever"; and also in another paper which I wrote for the Eighth International Congress of Hygiene and Demography held at Budapest in 1894 (see Comptes Rendus of the latter, Vol. II., p. 702), the conclusion of which was as follows: "The special measures which might be adopted against the propagation of yellow fever through mosquitoes must be left to the criterion of those who accept my theory, but the principal indications must be: 1. To prevent those insects from stinging yellow fever patients. 2. To destroy as far as possible the mosquitoes which have been infected, bearing in mind that in close spaces a temperature of 50° C. is sufficient for that purpose. 3. Finally, to consider any place unsafe so long as the last mosquitoes which have stung yellow fever patients may be alive in it; from thirty-five to forty days being the term of their existence under the most favourable circumstances."
>
> Despairing of ever obtaining a fair investigation of my theory, such as I had repeatedly solicited, but at the same time encouraged by the results which I had obtained even with my imperfect methods, it now occurred to me that I might be more successful in persuading my colleagues to try a plan for stamping out yellow fever which I had formulated in my own mind. I therefore took the opportunity of Koch's suggestions concerning malaria in 1898 to insert an outline of my plan as the conclusion of a paper which I read before the Academy of Sciences in November of the same year. I then translated this paper into English, with a more detailed account of my plan, and showed it to several officers of the American Army and Navy stationed in Havana in December of 1898. Finally, this same paper was published in the *New York Medical Record* of May 27th, 1899. I must ask you, gentlemen, to let me quote the last paragraphs of that publication. These were my words:—
>
> "Why should not the houses in yellow fever countries be provided with mosquito-blinds, such as are used in the United States as a mere matter of comfort, while here it might be a question of life or death? The mosquito larvæ might be destroyed in swamps, pools, privies, sinks, street sewers, and other stagnant waters in which they are bred, by a methodical use of potassium permanganate or other such substances, in order to lessen the abundance of mosquitoes; but the most essential point must be to prevent those insects from reaching yellow fever patients, and to secure a proper disinfection of all suspicious discharges, in order to forestall the contamination of those insects. Well-ventilated hospitals should be built upon high grounds, with no stagnant waters nor marshes in their vicinity; doors and windows protected by mosquito blinds; a good system of drainage and sewerage; and facilities for destroying any mosquitoes or larvæ which might be found within the building. Only the upper storeys should be occupied by the sick, and none but yellow fever patients and such malaria patients as are considered immune against yellow fever should be admitted. The examination for admission might be carried out in a separate building, and a separate department devoted to the suspicious cases under observation.
>
> "With such hospitals at hand, and an efficient board of health that would see to the proper arrangements for patients who could be left at

their homes, and general sanitary improvements within and around the principal cities, there can be no doubt that yellow fever might be stamped out from Cuba and Porto Rico, and malaria reduced to a minimum. It would then be the business of the port and quarantine officers to prevent the introduction of fresh germs."

Every word of that prophecy has now come true, and I appeal to Major Gorgas himself to say whether in the accomplishment of his admirable work, which has now culminated in the unquestionable stamping out of yellow fever from Havana, he has resorted to any measures which do not come within the scope of the programme set down by me in 1899. If this be so, am I not right in assuming that, if my plan had been carried into effect by the military government at that time, Cuba might have been rid of its inveterate enemy, the yellow fever, two years before the arrival of the United States Military Yellow Fever Commission in Cuba? The man who could do it was already here; and you may be sure that if the experiment had been entrusted to Major Gorgas, unconvinced though he was at that time, he would have displayed the same earnestness of purpose and special talents for planning out the best system of attack and defence against the mosquito which he did two years later, with the brilliant results which have earned for him world-wide renown. He would have acquainted himself with the methods which have been most successful in fighting the mosquito pest in the United States—petroleum for killing the larvæ and the pyrethrum fumes for destroying the winged insect. He would have formed his mosquito brigades and his squads for placing mosquito-proof screens upon every door and window of the sick-room, as well as in the yellow fever department of every hospital. As the propagation of the disease would show signs of decreasing, his faith in the method, and consequently in the theory, would have become strengthened, and final success would have been assured. Success obtained in this manner would have been a great loss to science, it is true, since the crucial experiments of the United States Yellow Fever Commission might in that case have been omitted. From the sanitarian's standpoint, however, the result would perhaps have been considered more satisfactory, inasmuch as 400 lives could have been saved in 1899 and 1900.

Now, in appearing before the London School of Tropical Medicine in 1909 to speak on these subjects, I contend that Professor Osler should not have omitted the name of Dr. Finlay, the only man who between 1898 and 1900 could say and do these things. The only man at that time, and in the history of the past, was this great Antillean who, like Alexander Hamilton, combined in his fertile mind the ancestral traits, the power of reasoning well and persistently of the Scotch, together with the lively imagination of the French.

I am, Sir, yours faithfully,

JUAN GUITERAS,
Director of Public Health, Havana, Cuba.

*** It is probable that the theories of Beauperthuy had already been rife amongst the medical men in the West Indies and on the mainland. Beauperthuy and Finlay will stand bracketed together, just as Harrison and Carter do. It is open to everyone to examine the respective writings of both Beauperthuy and Finlay. Both were original thinkers, and both came to the same conclusions, but Beauperthuy formulated his opinions earlier; Finlay coming later expressed his views more clearly and in a way more in conformity with modern thinking.—ED. L.

To the Editor of THE LANCET.

SIR,—The omission of Dr. Finlay's name was a pure inadvertance for which I am very sorry. His work, of course, on the subject, has been all important.

I am, Sir, yours faithfully,

WM. OSLER.

THE REPRESENTATION OF MIDWIVES ON THE CENTRAL MIDWIVES BOARD.

To the Editor of THE LANCET.

SIR,—The Incorporated Midwives' Institute wishes to call the attention of all certified midwives to the Amending Bill of the Midwives Act now before the House of Lords. It is generally recognised that midwives, of whom there are nearly 30,000 on the Roll, are most inadequately represented on the Board that governs them.

It was through the efforts of the Midwives' Institute that any representation of midwives was secured in the Bill of 1902. In spite of much opposition the Institute obtained nomination of a representative (a medical practitioner) to the Central Midwives Board. After six years' experience of the working of the Act and a very large increase in the numbers of the Midwives' Institute and its affiliated associations, it is evident that the time has come to claim more representation of midwives, and the Institute is now asking for two nominees, one of whom shall be a midwife.

The Midwives' Institute is in no way opposed to the principle of Direct Representation, if practicable; but as that would involve the election by ballot of a certified midwife by the 30,000 midwives on the Roll, it hardly seems at present to come within the range of practical politics. The Midwives' Institute therefore appeals to bodies and societies of midwives to coöperate by affiliating with the Midwives' Institute, in order to participate in the nomination and election of a representative on the Central Midwives Board; in this way obtaining direct representation of their members.

The interests of the practising midwives will at present be best secured by such representation through associations united to one centre, and it is greatly hoped that the younger members of the profession will help to consolidate the work of the pioneers. Ultimate success depends on the solidarity of a whole profession united in a common cause—viz., the protection of the lives of mothers and their children, the improvement in the status and training of the midwife being a necessary corollary.

I am, Sir, yours faithfully,

R. P. FYNES-CLINTON,
Secretary, Incorporated Midwives' Institute.

12, Buckingham-street, Strand, W.C., June 10th, 1910.

*** We publish on p. 1699 a leading article upon the whole subject.—ED. L.

TWO CASES OF BLACKWATER FEVER.

To the Editor of THE LANCET.

SIR,—I have read with great interest the description by Major D. G. Marshall, I.M.S., of a case of blackwater fever in THE LANCET of May 14th, p. 1333, and Dr. C. F. Harford's interesting letter upon the subject in THE LANCET of May 28th, p. 1498; and I should like, if I may trespass upon your valuable space, to quote from my small experience two cases that have occurred in my practice during the last six months, which seem to confirm Dr. Harford's views.

An officer of the West African Regiment arrived home on leave at the end of October. He had one slight attack of malaria on the coast, and had been taking quinine sulphate (2½ grain tabloids) upon the regularly intermittent principle ever since. On his voyage home he continued taking quinine till he reached the Islands, but, unfortunately, he followed the usual custom and dropped it then. I examined him the day after his arrival at his father's request, and passed him as quite sound. Two days later he felt ill, and I went to see him. He had mild jaundice and severe backache, some vomiting, and a temperature of 102° F.; there had been no rigors or sweats. So he remained for seven days, the jaundice and temperature diminishing, but the feeling of illness and backache increasing. There were no rigors, but frequent and drenching sweats, especially when he dropped off to sleep, and of such severity that his clothes had to be changed every two or three hours. There were no other physical signs. On the seventh day, at 3.30 P.M., actually as I was taking his blood to examine for malaria, the characteristic shivering began, and the typical paroxysm followed, going through the usual stages and ending about 10.30 P.M. I gave him 10 grains of quinine and followed it by 2½ grains night and morning, and during the rest of his leave he had no more attacks. I found the parasite in the blood.

The second case was a civil servant from Burma who had had several attacks of malaria and two slight attacks of bloody urine, which had lasted only a few hours and which he was told by a doctor in Burma were due to "malaria affecting the kidneys." Like many men in Burma, as opposed to West Africa, he was in the habit of taking quinine in large and irregular doses. He had fever before leaving Burma to come home on leave after three years out there and had hoped to regain his health on the voyage home. However, he felt so ill that instead of breaking his journey on the continent he came round by sea and landed in England on May 14th. On May 15th in despair he took 30 grains of quinine sulphate, as "quinine is no good unless it makes one's head buzz, and that means a big dose." At midnight on the 16th he had a rigor and passed "bloody urine." I saw him about 10.30 A.M. on the 17th; he was anæmic, jaundiced, and sweating, vomiting everything he took, and passing porter-coloured urine. There was no hiccough, but a good deal of headache and mental anxiety, owing to

knowledge of the dangerous nature of his illness. Temperature 102° F.; pulse 84 and good.

Dr. C. W. Daniels of the London School of Tropical Medicine was kind enough to see him with me next day, and out of his vast experience to give his valuable advice. The prognosis in his opinion was extremely favourable, provided that good diuresis could be maintained, because dilution of the urine with an equal quantity of water rendered the mixture almost transparent. I found the parasite in the blood on the 17th (sub-tertian variety), but none on the 18th as is usual. The urine, which gave the usual tests for blood and showed a very heavy deposit upon standing, contained many granular casts, but no red blood corpuscles. No quinine or purgative was given, but 2 ounces of fluid every quarter of an hour. The urine was passed at the rate of 4, 3½, 4, 4½ pints respectively in successive periods of 24 hours' duration, and at the end of 84 hours (3½ days) after the initial rigor showed no chemical trace of blood. The hæmoglobin of the blood on the third day of the illness was about 70 per cent., the lips, gums, and nails were bloodless, and loud hæmic bruits were audible all over the præcordium. To-day (May 31st) he is feeling very well and looks it.

Out of my very limited experience it seems to me that these two cases definitely support Dr. Harford's views: (1) Quinine is essential for malaria and malarial subjects; (2) small regular doses should be used, as in Africa, not large irregular doses, as in Burma; (3) regular daily dosage is better than regularly intermittent dosage; and (4) regular dosage should be continued for some considerable time after arriving in England.

As regards blackwater fever, which seems to be becoming more and more every year a disease with which even the general practitioner may be called upon to deal, it is important to remember: (1) The disease is a hæmolysis and not a hæmorrhage; (2) the great danger is suppression of urine owing to clotting of the blood in the renal tubules; (3) much fluid means much urine and safety; (4) the first 48 hours are the critical ones, in which all depends upon treatment; and (5) alcoholic stimulation is not contra-indicated as in hæmorrhage, and is often imperative.

I am, Sir, yours faithfully,

Fleet, Hants, May 31st, 1910. J. E. FRERE.

"A CASE OF LYMPHATISM."

To the Editor of THE LANCET.

SIR,—In the opening paragraphs of the article published in THE LANCET of May 14th, p. 1347, under this heading, Dr. L. P. Burt and Dr. J. R. Collins describe a condition in which there was noticeable enlargement of the thyroid gland together with tachycardia and dyspnœa. "The thyroid gland formed a large rounded tumour in the neck, larger on the right side than the left. The pulse varied from 100 to 150 per minute. On admission there was great dyspnœa." No attempt is made to furnish any explanation of the rapid supervention of urgent dyspnœa. The account of the necropsy states that there was no evidence of compression of the trachea, and we are left without any explanation of the urgent dyspnœa which called for the operation of partial thyroidectomy.

Passing to consideration of the cause of death, we have the statement that "the heart apparently ceased to beat five to seven minutes after the cessation of respiration," while a little lower down, in commenting upon the mode of death in cases of lymphatism, the following view is expressed: "It seems certain that there is present in these cases of lymphatism a morbid susceptibility to shock, and that a stimulus which in a normal subject would be quite harmless may give rise to a fatal inhibition of the heart."

The authors seemingly conclude that death was due to the effect of chloroform inhalation acting upon a patient subject to a condition of lymphatism, and I would call attention to what seems an important omission in the report of such a case. No mention is made of the length of time during which chloroform narcosis had been maintained prior to the supervention of death. Seeing that their publication had in view the demonstration of a special inability on the part of the subjects of lymphatism to withstand the deleterious effects of chloroform inhalation, it might, I think, have been expected that this point would have been made clear. The authors seemingly hold the opinion that the predisposing cause of death in the case they describe was without doubt a condition of lymphatism, but they have supplied no satisfactory proof that such was in reality the case.

They lay considerable stress upon what they consider an abnormal hypertrophy of the lymphatic tissues contained in the mucous membrane of the alimentary canal and of the mesenteric lymphatic glands. I would venture to ask with what knowledge it is possible to arbitrate between such an hypertrophy as may be looked upon as compatible with a normal state, and such a condition of overgrowth as should be rightly held to constitute evidence of a pathological state.

I am, Sir, yours faithfully,

EDGAR TREVITHICK, M.D. Cantab.

MEASLES AND THE POST-OFFICE AUTHORITIES.

To the Editor of THE LANCET.

SIR,—May I be permitted to add to Dr. Collier's letter in a recent issue that modern text-books support his practical experience. In the latest issue of a popular text-book on "Sanitary Law and Practice"[1] I find the following: "The infection of measles ..... is not commonly conveyed by healthy persons, hence it is unnecessary to exclude from school the children of infected households if they have themselves had measles."

Again, Washbourn and Goodall, second edition, 1908 say: "It is spread *chiefly* in a direct manner by those suffering from it, but there is reason to believe that the infection *may* be harboured in fomites and conveyed by third persons." (The italics are mine.) It may be of interest here to mention that the experience of certain towns, amongst them Aberdeen and Edinburgh, which abandoned the notification of measles after a trial in each instance of over 20 years, shows how little effect at present administrative measures have on the control of this formidable disease, the reduction of whose huge indirect mortality is exercising the minds of all medical officers of health, and certainly merits the enforcing of more drastic measures to secure that end. Amongst such measures I would suggest the classification of measles with such diseases as scarlet fever, diphtheria, &c., and the taking of proceedings under the Public Health Acts against such parents as wilfully expose children suffering from the disease to the risk of the general community.

I am, Sir, yours faithfully,

June 10th, 1910. J. P. CULLEN.

SPINAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I note in THE LANCET of May 7th under the heading "Spinal Anæsthesia" that your annotation says, "In the *Indian Medical Gazette* the fatality was clearly attributed to the excess of strychnine employed."

Surely, in his anxiety to exculpate novocaine the writer has worded his remark badly. A reader would gather that the dose of strychnine in this case was in excess of what is usually given with safety. Probably what he meant to convey was that death was held to have been possibly due to excess of strychnine having reached the nervous centres of respiration—not implying quite the same thing as the administration of an overdose of strychnine. It is not the particular drug employed nor the size of the dose that is the uncertain factor in spinal anæsthesia, but the difficulty of controlling its distribution.

I am, Sir, yours faithfully,

P. C. GABBETT,
Madras, India, May 25th, 1910. Major, I.M.S.

THE MATRONSHIP AT ST. BARTHOLOMEW'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—The recent appointment to the matronship of St. Bartholomew's Hospital has occasioned much adverse criticism both in medical circles and from nurses holding the certificate of the hospital. May I, as one of those nurses, briefly explain why we consider we have just cause for objection? Firstly, the age limit of 40 announced in the

[1] Robertson and Porter, second edition, 1909, p. 252.

advertisement notifying the vacancy excluded the great majority of nurses trained at St. Bartholomew's Hospital who are now holding positions as matrons of important hospitals, and have earned for themselves high reputations as administrators and teachers of nurses. Promotion in these days of keen competition is slow, and few nurses have, under modern conditions of training, held positions of importance in the nursing world, such as would qualify them for the matronship of the first Royal hospital before that age.

We consider also that as the nursing school has been organised for over 30 years and has trained pupils who have proved themselves capable of holding positions of high responsibility in all parts of the world, the precedent, adopted with advantage in making appointments to the medical staff, should be followed, and a candidate selected, where possible, trained in the school and who holds its methods and traditions in honour. This course has been followed in recent years in connexion with appointments to the matronship of St. Thomas's Hospital, King's College Hospital, Guy's Hospital, the Royal Infirmary, Edinburgh, and the Royal Infirmary, Glasgow, and it is manifest that if the other great training schools of the kingdom adopt this just method of conferring preferment upon their own pupils, while the authorities of St. Bartholomew's Hospital do not recognise the claims of their nurses for consideration, or the importance of protecting the prestige of their own certificate, the school will descend to a position of second rank.

Secondly, we hold very strongly that, if the election committee desired to appoint a lady to the matronship of the hospital trained in another institution, we had a right to expect they would have made a three years' certificate a *sine quâ non*, and not have gone out of their way to select a lady from an institution which certifies its pupils as proficient after two years' training, a standard now practically obsolete in this country. Since 1881 St. Bartholomew's Hospital has required of every pupil three years' probation in the wards of the hospital, followed by examination, before awarding its certificate, and no nurse can even be appointed a sister in the hospital until that certificate is gained. For this reason the St. Bartholomew's certificate and its nursing school have the highest reputation all over the world—a reputation deservedly earned for it by generations of devoted pupils.

There is not a nurse trained at St. Bartholomew's but feels keenly the slur put by the election committee upon the standard maintained, and the quality of the training given them, under the direction of their late revered matron, Miss Isla Stewart, and on her 23 years' devoted service to the welfare of the hospital, in passing over every pupil of the school to which she devoted her life. We feel sure that in support of our opinions in regard to this appointment we shall have the sympathy of a very large majority of St. Bartholomew's men, who practise all over the country, who approve the Bart.'s system of training and employ its nurses.

I am, Sir, yours faithfully,

June 14th, 1910. F. G. S.

THE REBATE ON PROFESSIONAL MOTORS.

To the Editor of THE LANCET.

SIR,—The Finance Act is law, and has been for some time. The mode of assessment of motor cars has been altered, and medical men are allowed a rebate of one half on cars that are used for professional purposes. I have written to the Comptroller's Department of the L.C.C. but have had no reply. Can you tell me how they can be made to refund?

I am, Sir, yours faithfully,

June 10th, 1910. PANHARD.

*** The present licences expire on the last day of this month. We understand that the needful certificates are not yet ready, but these will be issued shortly by the Local Taxation Department of the London County Council for those who live in that area, and by the other county councils for their respective districts. With the certificates will be issued declaration forms, which, when filled up, should in the case of residents in the London area be forwarded to the Local Taxation Department, County Hall, London. These will then be investigated by the district local taxation officers, and when vouched for as correct by them an order on the Post Office will be issued for the amount of the rebate.—ED. L.

TOWN PLANNING AT LIVERPOOL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Liverpool, June 10th.

ABOUT two years ago in raising the question of a public abattoir for Liverpool there was occasion to recall the evil reputation that this great port had acquired during the first half of last century.[1] Indeed, so late as 1870 the average death-rate for the preceding ten years was 32·5 per 1000. The average death-rate during the five years 1903 to 1907 was 19·9 per 1000. Thus, though the death-rate still remains high, there can be no doubt but that an immense improvement has been realised. Naturally the progress achieved results from endeavours made in many different directions. No one public or private enterprise, however vast and far-reaching, could bring about such a change. Nor would it be easy to say which of the many improvements effected have had the largest share in bringing about the desired end. Yet there can be no doubt that the most dramatic fact of old Liverpool was its narrow courts, its cellar dwellings, with no drainage, hardly any water, and the 22,000 back-to-back insanitary houses that still existed in 1864. But what is also very remarkable is the fact that, while condemning and destroying insanitary areas in the congested parts of the city, the authorities did not wait for any Town Planning Act to take steps to prevent the creation of overcrowded districts in the as yet uninhabited surrounding of Liverpool. In fact, though an extensive planning scheme has been carried out, this was done before the adoption of the Town Planning Act.

In the first instance the municipality resorted to negotiation and persuasion. The landowners were shown that nothing could better contribute to raise the value of their land than the construction of wide and, where possible, of beautiful thoroughfares. In many instances there remained some fine old trees, and every effort was made to save them and include them in future gardens or shady side walks. But if some landowners were sufficiently perspicacious to appreciate these arguments, others were not. Though a good deal might be, and as a matter of fact was, accomplished by friendly negotiations, this only sufficed for the realisation of fragments of a general scheme. On the other hand, it was ample for experimental purposes. Thus if the municipality had gone to Parliament for powers to lay out thoroughfares at the landowner's expense and against his will which should be 80 feet wide, the demand would probably have been treated as unreasonable and brushed aside. As it was, the Liverpool authorities were able to approach Parliament with the established fact that roads 80 feet wide had been built, were more popular than older and narrower roads, and Parliament was therefore only asked to render obligatory what had already been done voluntarily and had proved satisfactory to all parties concerned. Thus a local Act was obtained by which roads laid out in areas to be newly developed must be 80 feet wide. Formerly the landlords gave land for roads 60 feet wide and constructed the roads. Now they were called upon to give land for roads 80 feet wide, but only to construct roads for vehicular traffic 35 feet wide. The remaining 45 feet were reserved for trees, grass, flower beds, and side walks. In some cases the amount of road work the landowner should supply has been reduced, the town obtaining more land in exchange. The law, of course, does not grant retrospective powers; the town cannot go back on what has already been done and widen existing streets without paying full compensation. The point gained is that henceforth the authorities can enforce the rule that new thoroughfares shall be 80 feet wide.

Gardens and Trees on the Road.

In practice, however, the town council of Liverpool has improved very considerably on what the law allows. Instead of 80 feet, a considerable part of the Queen's Drive is 108 feet wide, and Menlove-avenue, which is three-quarters of a mile long, is 114 feet wide throughout. In this case the expense was shared between the landlord, the tramway company, and the town. The centre of the space was paved for vehicular traffic and tramways, taking up 56 feet. On each side comes a paved side walk for pedestrians 3 feet wide, which will be used principally for getting in and

[1] See THE LANCET, August 22nd, 1908, p. 586.

out of conveyances. Then comes a border 13 feet wide for trees, grass, and flowers; a side walk 7 feet wide, and another border for plants and trees 6 feet wide. Altogether 29 feet on each side of the vehicular roadway are devoted to trees, vegetation, and side walks. Then only do we reach the domain of private property, where there will be still further gardens and trees before private houses rise up to interfere with the free circulation of the air and the direct rays of sunlight. As far as possible the new roads have been designed so as to include some fine trees. This was notably the case in the Larkhill-lane widening, where land with full-grown trees was purchased on either side and added to the now shaded and beautiful footways. Prescot-road was also widened 45 feet, and fine trees were saved which might have been cut down so as to build houses close up to the pavement of the thoroughfare.

How Landowner and Tenant Benefit.

The principle of the negotiations has been throughout to reduce the amount of road construction done at the landowner's expense and to obtain in exchange more width of land for the roads. Obviously from the public health point of view the chief object is to secure for ever the widest possible space between dwellings. To comply with hygiene and sanitary ideals there must be plenty of fresh air; the purifying rays of sunlight must be able to reach and bathe the walls of the houses. In securing these ends, so essential to the public health and happiness, the landowners have far more to gain than to lose. Whatever concessions they may be induced to make, and however severely the compulsory clauses of local Acts may deal with them, so long as the town continues to grow well-planned development will prove very much to their advantage. As an example, there is, for instance, the history of Princess-road. Some 20 years ago the ground here was let for grazing purposes at £3 per acre. To-day it can be sold on a building lease of 75 years at 6*s.* 9*d.* per square yard. If the authorities wanted to widen the road they would now have to pay 4*s.*, 8*s.*, and in some parts 14*s.* the square yard. Consequently new roads opening up new land for building purposes generally prove most profitable to the landowner; but the town authorities are right in seeing that the public health interests shall be well protected before aiding such developments. Above all, there must be no narrow thoroughfares, narrow backyards, and crowding of high houses built too close to each other. No such risk is present in the new suburbs now being opened up. Also it must be borne in mind that the width of a thoroughfare has a direct bearing on the architecture of the district. The moment a street is broad enough to obtain a good view of the houses that are on the other side of the way, the necessity of some architectural features becomes irresistible. Even if only modest houses at low rentals have to be built there will be some attempt to make a pleasing design. The obvious tendency is to build the better class houses in the broadest thoroughfares, only there is a natural limit, and if there are to be a great number of wide roads and avenues then there will not be enough wealthy people to inhabit them all. Consequently there may be in time such a large supply of new houses that the more modest purses will nevertheless be heavy enough to pay the lower rents likely to be charged in some of the fine avenues and roads where trees and vegetation abound and there is space enough to prevent any overcrowding.

The Liverpool Plan.

The plan on which these new roads are built is simple enough. Liverpool has for basis the Mersey, which is the port, and where now exist seven miles of docks. The tendency is to cluster as near as possible to the water side and the streets and houses stretch backwards inland in a fan shape. Half a wheel would represent Liverpool, the other half of the wheel being the Mersey, and the hub the centre of the city. The town planning consists of extending the spokes of the wheel into the as yet uninhabited parts of the surrounding country. Each spoke represents a thoroughfare starting from the centre to the outskirts. But to prevent too much traffic in the centre a circular road is in course of construction forming a hoop round the wheel and connecting the spokes while still at a considerable distance from the centre. This outer hoop is called the Queen's Drive and is the most important part of the scheme. The other roads are roads of access to the centre, spokes to the hub of the wheel, but these are for the most part elongations and widenings of thoroughfares that already exist. The Queen's Drive is new; it will enable a person starting from any point at a distance from the centre to drive round to the road by which he wishes to penetrate the centre, thus avoiding a good deal of cross traffic within the already congested central quarters. This hoop then that goes round the spokes of the wheel commences at Rice-lane and was built on to Cherry-lane, a distance of one mile, in 1904. The width is 84 feet. The second length was constructed in 1909, has the same width, and is three-quarters of a mile long, passing through the Walton district. Now comes another portion, also three-quarters of a mile, from West Derby-road across Lisburn farm, which will also be 84 feet wide and is not yet completed. From here by Black Horse-lane there is a length of one and a half miles for which all the necessary arrangements are not yet completed, and then we come to a magnificent road 108 feet wide and three-quarters of a mile long, commencing at the Childwall Priory-road. This is in course of construction and other similar stretches to the Woolton- and Allerton-roads are not yet complete. The Queen's Drive, it will be seen, will be several miles long and will connect all the outlying suburbs with each other.

Thus, in regard to town planning Liverpool is well to the fore. It has not to consider now what shall be done, but to complete what has been begun. In many parts sections of the scheme are successfully completed. On some of these new thoroughfares dwellings have already been erected and it was not necessary to wait long for tenants. Liverpool has suffered so keenly from the absence of any sort of town planning in the building up of the old parts of the town that it has shown a very natural determination to prevent the recurrence of any such fatal error. So far as I know, there is every reason to hope that new and greater Liverpool will be in the first rank among the large cities that intend to avail themselves of the principles embodied in what is called town planning.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

THE German Congress of Internal Medicine was held this year in Wiesbaden, Professor KRAUS (Berlin) being in the chair.

Diagnosis and Specific Treatment of Tuberculosis.

Professor SCHÜTZ (Berlin) said that the frequency of tuberculosis among cattle had doubled during the last 12 years. At one time the diagnosis of the disease as made by subcutaneous injection of tuberculin agreed very well with the results found after the animals were slaughtered, the amount of discrepancy being only 2 or 3 per cent. Recently, however, some foreign importers of cattle have materially lessened the value of this procedure by giving previous injections of tuberculin, the consequence being that in the year 1905 the tuberculin test gave a positive reaction in only 0·8 per cent. of the cases, whereas after the animals were slaughtered 24·7 per cent. of them were found to be tuberculous. Tuberculin might be employed otherwise than by subcutaneous injection, as, for instance, by the epidermal, the cutaneous, the intracutaneous, and the conjunctival methods of administration, but neither these nor the procedure by agglutination and precipitation have proved reliable. To destroy tuberculous cattle would be impracticable on the ground of expense. The administration of Behring's bovo-vaccine produced an immunity lasting for only one or two years, and large doses could not be used because tubercle bacilli might make their appearance in the milk.

Professor PENZOLDT (Erlangen) introduced a long and inconclusive debate upon the tuberculin treatment.

General Chemotherapy.

Professor EHRLICH (Frankfort) said that the investigations which he had been making in an endeavour to discover an internal disinfectant were now approaching completion. His new preparation, the chemical name of which was dichlorhydrat-dioxy-diamido-arsenobenzol, was also known

as "Preparation No. 606." It had been tried in the treatment of relapsing fever by Professor Iversen in St. Petersburg, who found that after a single intramuscular or intravenous injection of 0·2 or 0·3 gramme the spirilla completely disappeared from the blood. The relapses which occurred in 8 per cent. of the cases were very slight.

Dr. HATA (Frankfort), Professor Ehrlich's assistant, confirmed the statement that in animals the spirilla of relapsing fever disappeared from the blood after a single injection of the above compound, and that immunity was established, lasting for four days in the case of intravenous injections and from 35 to 50 days in the case of intramuscular injections.

Dr. SCHREIBER (Magdeburg) and Dr. HOPPE (Uchtspringe) reported the results which they had obtained in the treatment of syphilis and metasyphilitic diseases of the central nervous system. In 100 cases of recent syphilis and of metasyphilitic diseases a single intramuscular or intravenous injection of 0·3 or 0·4 gramme of Professor Ehrlich's compound caused disappearance of the symptoms and non-response to Wassermann's reaction in 92 per cent. of the cases. The syphilitic exanthem became in some cases at first a little darker, but then disappeared very quickly. Symptoms of intoxication were never marked; only an artificial exanthem and a temporary raising of the temperature happened. The fatal dose was 0·15 gramme for each kilogramme of an animal's weight, whilst the dose used for therapeutic purposes was only 0·008 gramme. The arsenic was usually excreted within four days, but in the case of paralytic patients 10 days might be required.

Vasotonin.

Professor MÜLLER (Berlin) reported the results of experiments which he had made with vasotonin, a compound consisting of urethane and johimbine. He found that in animals it produced a decrease of the blood pressure without congestion of the heart or troubles of the respiration. The blood pressure decreased because the blood flowed to the peripheral parts of the body, as was made obvious by the volume of the limbs increasing, whereas that of the kidney and the intestines diminished.

Dr. FELLNER (Franzensbad) said that the compound had been administered in 30 cases of hypertension, 1 cubic centimetre (= 0 01 gramme of vasotonin) being injected daily. The blood pressure became lessened in every case and various subjective symptoms which were complained of were considerably mitigated even in arterio-sclerosis of the brain.

Dr. STÄHELIN (Berlin) said that he had frequently used the preparation with success in the clinic of the University of Berlin. The blood pressure decreased considerably, as a rule, after a single injection and kept so for several days or even weeks. One patient lost his attacks of angina pectoris; all felt very much relieved, and there were only a few who felt a sensation of heat in the head and giddiness just as after inhaling nitrite of amyl. He was of opinion that vasotonin marked a decided advance in the treatment of arterio-sclerosis.

Professor KREHL (Heidelberg) said that a decrease of blood pressure did not necessarily denote an improvement in the patient's condition. He recommended great caution in the use of medicines which acted powerfully on the physiological processes regulating the blood pressure.

Acute Overstrain of the Heart.

Professor SCHOTT (Nauheim) reported some experiments which he had made on acute overstrain of the heart. In dogs he resected three ribs on both the left and the right side, so that after the healing of the wound he was able to palpate the whole circumference of the heart and to examine the movements of the diaphragm. In accordance with observations which he had formerly made on athletes and on cyclists, he found that mere walking did not cause an alteration of the heart, but that quick running produced a temporary dilatation, and running until exhaustion ensued was followed by permanent dilatation of the heart perceptible to both sight and touch.

The Origin and Treatment of Secondary Anæmia.

Professor GERHARDT (Basle), speaking on the subject of secondary anæmia, said that it had two different causes—namely, (1) loss of blood by hæmorrhage, and (2) destruction of the blood by toxins. It was probable, though not quite certain, that deficiency of fresh air and of light might bring on anæmia. Derangements of the metabolism of iron and a decrease of the absorption of the compounds of iron contained in the food were also causes of anæmia. According to Professor Sahli, iron could be absorbed only when the contents of the stomach had an acid reaction, and an absence of gastric acidity was the rule in grave and in pernicious anæmia. In malaria, syphilis, and cancer, the destruction of erythrocytes was proved by the presence of urobilin in the urine and by the red colour of the bone marrow. The anæmia of pregnancy and the puerperium was generally recovered from in about 50 per cent. of the cases, as normoblasts and megaloblasts were seldom present in the blood. Many cases of anæmia were accompanied by tumours of the spleen; certain diseases of the blood obviously proceeded from disease of the spleen and might be successfully treated by removal of that viscus. It was probable that, in these circumstances, the spleen had an inhibitory influence on the formation of the blood, but did not destroy it. A second group of anæmias was produced by poisons, such as chlorate of potash, aniline, and nitrobenzol, and experimentally by pyrogallol, phenylhydrazin, and hydroxylamin; the erythrocytes were considerably reduced in number by the action of these poisons. Professor Tallquist has been able to produce anæmia by the administration of extracts obtained from worms and also by the administration of oleic acid. A hæmolytic toxin could also be produced from the gastric and intestinal mucosa and from cancer tissues. There was a difference between the anæmias caused respectively by venesection and by poisons—namely, that in the former the resistance of the erythrocytes became smaller by repeated venesections whereas in the latter it became greater; in the former the blood obtained by venesection showed an increase of oxygen respiration, but in the latter not. Two groups must be distinguished in pernicious anæmia, one of them being produced by a functional defect of the bone marrow, and the other by a destruction of the blood. The sovereign remedy for anæmia was iron, but in pernicious anæmia arsenic must be given. The serum treatment of anæmia was still in the experimental stage.

Dr. SCHAUMANN (Helsingfors) reported the further course of 72 cases of anæmia which had been caused by bothriocephalus and were first published in the year 1894. Only 16 of them were at present in fairly good health; some had died from renewed attacks, and three were suffering from pernicious anæmia, notwithstanding the removal of the parasites.

Professor SCHMIDT (Halle) said that he doubted whether oleic acid was really an exciting cause of anæmia. On examining the mucosa of the gastro-intestinal canal in pernicious anæmia he had found powerful toxins and numerous cells showing fatty degeneration.

Professor KLEMPERER stated that he had found no difference between the mucosa of a normal intestinal canal and that of a patient suffering from pernicious anæmia.

Dr. KUHN (Biebrich) said that a morbid condition similar to pernicious anæmia might be produced by atoxyl; this made it very likely that the disease was caused by a hæmolytic toxin.

Professor MOHR (Halle) spoke against the theory that oleic acid destroyed the erythrocytes.

Infantile Paralysis.

Dr. KRAUSE (Bonn) described the acute infectious stage of infantile paralysis as observed by him in 780 cases during the recent epidemic in Westphalia and the Rhenish province. The majority of the patients were children in their second year, and the epidemic was at its height during the month of October. In the acute stage it was necessary to discriminate between the paralysis and the general symptoms, consisting of sore-throat and gastro-intestinal catarrh. As a rule only a fraction of the paralysed muscles were restored to their normal condition. The lumbar fluid was limpid. Death was generally caused by paralysis of the respiratory muscles on the third or fourth day. The mortality varied from 12 to 20 per cent.; complete recovery occurred in only from 15 to 18 per cent. of the cases.

Dr. MEINICKE (Hagen) said that the virus of infantile paralysis was very resistant against glycerine, high temperature, and putrefaction. It had hitherto been found only in the human body, especially within the central nervous system, the spleen, the blood, and the lumbar fluid. Experiments on animals showed that it had an incubation period varying from 8 to 12 days.

Dr. RÖMER (Marburg) said that by the experiments of Dr. Landsteiner on monkeys it has been ascertained that the incubation might last from 5 to 16 days, and that the nasopharynx was the place of entry. From there it penetrated through the lymphatic vessels into the central nervous system, where it produced a meningo-myeloencephalitis localised in the anterior cornu of the spinal cord. The disease was never contracted a second time. The virus was destroyed by a temperature of 55° C., as well as by carbolic acid and menthol.

Pathology of Gout.

Dr. UMBER (Altona) said that he had found that after an intravenous injection of monourate of sodium a healthy person excreted 95 per cent. of that substance within a short time, but some gouty patients excreted none at all, while others excreted variable amounts not exceeding 24 per cent., and that only very slowly. Dr. Umber concluded from his observations that the essential condition of gout was a retention of uric acid within the tissues of the body.

Dr. GUDZENT (Berlin) stated that the solubility of monourate of sodium was considerably increased by the emanation of radium; it was neither the α nor the β rays but a product of disintegration which had this effect. He had also discovered a body yielding the murexide reaction without being precipitable; it was probably the isomeric form of uric acid. He saw in three gouty patients the uric acid disappear from the blood under the influence of radium emanation and the tophi at the same time became smaller.

Dr. SCHITTENHELM (Erlangen) pointed out that the small excretion of uric acid in gouty persons after an injection of it had been given was not identical with a retention. He had found, together with Dr. Brugsch, that the essential feature in gout was not a renal retention but a slow destruction of uric acid; this was confirmed by the fact that a gouty person who had been taking food free from nuclein produced after the administration of nucleinate of sodium a smaller quantity of uric acid than healthy persons did. Gouty patients excreted the uric acid promptly after intramuscular injection.

Professor MINKOWSKI (Breslau) asked why gouty persons, notwithstanding the increase of uric acid in their blood, excreted a smaller quantity than healthy persons. He stated that the increase of uric acid in the blood of gouty persons had been ascertained by Dr. A. E. Garrod of London.

Professor KRAUSE said that the discoveries of Dr. Schittenhelm and Dr. Brugsch with respect to an increase of uric acid in the blood of gouty persons after they had been taking food free from purin were new and important and not to be confounded with Dr. Garrod's statements.

Professor KLEMPERER (Berlin) said that after radiogen baths he had seen improvement, but not any actual recoveries.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The University of Liverpool: The Benefactions by the Late Professor James Campbell Brown.

THE late Dr. James Campbell Brown, professor of chemistry in the University of Liverpool, by the terms of his will bequeathed to the professors of chemistry in the University of Liverpool and their successors for the time being his collection of old alchemical and similar books at present [September, 1905] on the bookshelves in his rooms at the University, and of which two card catalogues exist, unless he should have already disposed of them, to be cared for by them, kept together as a collection, and regarded as a nucleus of a collection for the professor's private room. But should the Senate not approve of this place and manner of keeping the books they are to be sold and the proceeds given to the Liverpool Governesses' Benevolent Society to increase the "Mrs. Campbell Brown Annuity." He bequeathed a sum sufficient to produce an annual income of £50, to Liverpool University to found an advanced chemical scholarship to be called "The Campbell Brown Scholarship," to aid students of sufficient ability and attainments to continue their studies after the third year of special study to be trained in the methods of chemical research. This scholarship shall not be payable to one preparing for the ordinary B.Sc. or M.Sc. examinations until free from the trammels of examination for the degrees, or any corresponding or lower degrees, and shall be held at the University of Liverpool. He also bequeathed a sum sufficient to produce an annual income of £800 to the University of Liverpool upon trust for the endowment of a chair of chemistry, in addition to existing chairs, to be called "the Campbell Brown chair," subject to the condition that the University shall pay a salary to the holder of the chair of not less than £800 per annum, and, in addition, two-thirds of the fees of his students for the teaching of industrial chemistry; or if a chair shall have been endowed, then either for a chair for the teaching of agricultural chemistry or a chair of some other branch of industrial chemistry. The professor of the chair is not to engage in ordinary analytical or consulting work, nor to undertake commercial work, although he should be allowed to engage in investigations connected with new processes of manufacture or other important industrial research. The bequest is subject to the conditions that the University undertakes to provide a suitable lecture-room and laboratories, giving ample accommodation for 20 advanced students, with a sufficient number of accessory and smaller rooms fully equipped for this special research and teaching, and to provide the cost of apparatus and material assistance to render successful the work of the chair; and he left a sum of £5000 to the University upon trust, to place the income at the disposal of the "Campbell Brown" professor for the time being towards the cost of his apparatus and material. If the University of Liverpool shall not accept the bequest for the endowment of the chair on these conditions, the whole sums are to be given to the University of Manchester to endow a "Campbell Brown" chair of music. Further, the testator's wife has power during her life, if she shall see good reason for so doing, to divert this bequest from the University of Liverpool to the University of Manchester. The residue of his property he left upon trust to found a series of entrance scholarships, each of the value of £60 per annum, to be held at the University of Liverpool, tenable for three years and renewable for a fourth year on the recommendation of the professors of the faculty. These scholarships are to be awarded at the entrance examination, the subjects to include Latin and German, especial attention being given to German, and for students who appear to be likely to succeed in chemical research. Such student shall proceed to a degree in the honours school of chemistry, and he is to forfeit this scholarship if he shall fail in any year from lack of diligence or ability to keep up his work to the standard required for a first-class honours degree. The will has been proved at £43,101, and the total amount available for charitable purposes would appear to be about £35,000.

National Association for the Prevention of Consumption.

The Lord Mayor formally opened a Tuberculosis Exhibition at St. Martin's Hall, Scotland-road, Liverpool, on Wednesday, June 15th. It will remain open for ten days, each day from 10 A.M. to 10 P.M. A popular lecture on "The Prevention of Consumption" was given by Sir James Barr, M.D. Special lectures will be given each evening at 8 P.M. by well-known medical men.

June 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Commemoration Day at the University of Glasgow.

COMMEMORATION Day, a biennial event, was observed in the University of Glasgow on June 9th. There was Divine service in the Bute Hall at 10.30 A.M., followed by the customary oration. The Rev. Dr. John Smith gave the oration, his subject being "Andrew Melville, Poet, Patriot, Reformer." Thereafter honorary degrees were conferred on various distinguished graduands. A reception in commemoration of "Founders' Day" was held at Queen Margaret College during the afternoon, and in the evening the honorary graduates were the guests of the University at dinner.

Suggested Epileptic Colony for Glasgow.

Glasgow parish council last week received the report of a deputation which had been appointed to visit colonies in England for sane epileptics. The deputation suggested that the projected accommodation should be of the colony type.

It is believed that there are some 200 epileptics for whom provision would require to be made. The most economical provision, the deputation stated, would be in the form of villas to hold 50 patients each, and, other things being equal, of the type of one-storey buildings seen at Monyhull, near Birmingham. In addition there would be the necessary administrative centre, laundry, central kitchen, farm, and general hall, attached to which latter they would advocate workshops with an abundance of light, air, and space. The reason for having large workshops is that the employment of patients would be continuous in all kinds of weather. In good weather they would be employed out-of-doors at farm and garden work, and in bad weather they could be employed in central workshops at the necessary repairs for the institution or in attending to the wants of the institution. Unremitting occupation, the deputation added, was the very best thing for warding off epileptic attacks and conducing to a contented and peaceful state of mind. It was true that many epileptics were not good workers, but from observation of numerous cases of epilepsy the deputation was confident that personal supervision of the individual wants of epileptics, while giving them employment, would conduce to a better state of affairs in that respect.

Death of Dr. P. A. Smith, Glasgow.

Dr. P. A. Smith, a prominent medical practitioner of Glasgow, died last week at his residence in Crosshill. Born in Glasgow 60 years ago, he received his early education at Dumbarton Burgh Academy. He graduated M.B., C.M. at the University of Glasgow in 1881 and M.D. in 1896. After his first graduation he acted as house physician in the Royal Infirmary, Glasgow, and commenced practice in Dumbarton. Early in his career, however, he returned to Glasgow, where he carried on a large practice up to the time of his decease. He held many important appointments in his time, most of them associated with the various Roman Catholic institutions in the city. He was also a justice of the peace for the county of the City of Glasgow, and for some years he was a member of Govan parish council. On the occasion of his retirement from practice in the Anderston district of the city three years ago he was entertained by his friends to dinner and presented by them with an illuminated address. The following year he was entertained again by his friends and received a presentation on the occasion of his attaining his semi-jubilee in practice, the company on that occasion including several Scottish Catholic bishops. Dr. Smith's wife—a sister of Archbishop Maguire—predeceased him 14 years ago. He is survived by three sons and three daughters.

Death of Dr. P. G. Bannister, Montrose.

The death took place very suddenly on June 9th in Montrose of Dr. P. G. Bannister. Dr. Bannister was born in Jamaica 40 years ago, and qualified as M.D. in Kingston, Ontario. On coming to this country he obtained the diplomas of the Edinburgh and Glasgow Colleges and commenced practice in Montrose five years ago. He was unmarried.

Strichen Hospital for Infectious Diseases: Committee of Inquiry Appointed.

At a meeting of the Deer district committee held at Maud on June 4th a committee was appointed to inquire into matters connected with the infectious diseases hospital at Strichen. A minute of a meeting of the committee of management of the hospital, held at Maud on March 26th, stated that there was submitted a report by the medical officer of health, dated March 9th, with reference to the case of a child, notified by Dr. J. H. Stephen, Strichen, to be suffering from scarlet fever and removed to the hospital. This case the hospital medical attendant considered doubtful, and 19 days after admission caused the parents to be informed that when admitted the child was not suffering from scarlet fever. After discussion it was resolved that if the medical attendant had doubt as to the correctness of the diagnosis made by Dr. Stephen it is to be regretted that he did not at once communicate with the medical officer of health as prescribed by the regulations, and, seeing the medical officer was not consulted, that he should have caused intimation to be made through the matron to the parents of the child. The clerk was instructed to intimate this resolution to the medical attendant. The minute of a meeting of the same subcommittee held on April 16th stated that a letter from Dr. G. S. Trail, medical attendant at Strichen Hospital, to the clerk, dated April 1st, animadverting on the terms of the minute dated March 26th, in so far as it stated that he had caused the parents of the child to be informed that when admitted to the hospital the child was not suffering from scarlet fever, was submitted and read. The minute, of which an extract was furnished to Dr. Trail, was based on a report by the medical officer of health of the county to the effect stated, which has been found to be substantially correct, and the subcommittee was satisfied that the minute was not open to the unwarranted language employed by Dr. Trail in his letter to the clerk, and that neither in that nor in any previous minute had the committee shown any discourtesy towards Dr. Trail. The clerk was instructed to intimate this resolution to Dr. Trail. At the meeting on June 4th exception was taken by one of the committee to the minute of the hospital subcommittee of March 26th, and after much discussion it was finally decided to appoint a committee, which would confer with the subcommittee of management in connexion with the hospital, and investigate the whole facts and the complaints of Dr. Trail alluded to in the minutes of March 26th and April 16th.

June 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ireland and the Midwives Act.

THE fact that an amending Bill to the Midwives Act is likely to come before Parliament in the near future has naturally raised the question as to whether the application of the Act should be extended to Ireland. So far, however, the point has hardly been considered, and the profession has not formulated any opinion on the subject. The Irish Branch of the General Medical Council has put forward a demand for the extension of the Act, and, as was announced in THE LANCET of June 11th, p. 1650, the Ulster Branch of the British Medical Association has expressed a similar wish. No other representative body has considered the question, though the Irish Medical Association and the Leinster and Connaught branches of the British Medical Association have all met within the past few weeks. The current number of the *Journal of the Irish Medical Association* invites the opinions of members of the Association, and prints an editorial paragraph and a letter from Dr. F. W. Kidd to open the discussion. Dr. Kidd has a right to speak with authority on matters concerning obstetric practice, and his argument is, on the whole, opposed to the extension of the Act. He holds that on the grounds of utility, or public safety, there is little need for the Act in Ireland. The training of midwives for registration, if the regulations which govern their training should remain as at present, would seriously interfere with the teaching of students in the Dublin maternities. As a result the prestige of Dublin as a school of obstetrics would suffer. The editor, whose opinions are also adverse to the measure, points out that the Act has not worked very satisfactorily in England, and therefore Irish medical men are right to be cautious.

The Working of the Tuberculosis Act.

In his annual report on the health of Armagh Dr. Hampton Gray, medical superintendent officer of health, remarks:—

> Your Board adopted Part I. of the Tuberculosis Prevention (Ireland) Act. Unfortunately the powers conferred by the Act are of no practical advantage in helping to eradicate tuberculosis. The country is so well informed with respect to all the dangers arising from the disease, the time has now arrived for the Local Government Board to call upon Parliament to pass an Act making notification of all cases of lung tuberculosis imperative. The present Orders for Notification, based as they are on the Notification of Tuberculosis Act, have so many restrictions, and so many loop holes for those desirous of not notifying, that in reality both Act and Orders are dead letters, and will not effect that which was expected of them. The notification should not contain any words which signify that the sanitary authority are to make no inquiries concerning the sanitary surroundings of the dwelling in which consumptive is living. On the contrary, full powers should be given to the sanitary authority to investigate everything in connexion with these cases.

These comments are made after experience of the Act, and similar opinions are held elsewhere. The conditions under

which notification is to be made as laid down by the Local Government Board are so narrow that they render the notification provisions of the Act nugatory.

Lisburn Workhouse Fever Hospital.

The Local Government Board has just given its decision in reference to the circumstances attending the deaths of two children in the fever hospital of the Lisburn workhouse, which formed the subject of a recent inquiry by one of its medical inspectors. In reference to one of the cases it does not consider that there was any neglect of duty on the part of the medical officer; in reference to the other it finds that the medical officer's attendance was unduly delayed, but as he was as a rule regular in his attendance, the Board does not think that any serious notice on its part is called for. It recommends that the medical officer's residence be connected with the workhouse by telephone, and also that the infirmary and fever hospital should be in telephonic communication with the master's office, so that either place could be switched on to the medical officer's residence in case of need.

The Anti-tuberculosis Campaign.

As there is no likelihood of county bacteriologists being appointed at present in order that a correct and early diagnosis of consumption should be made, Dr. Samuel Agnew has got the Lurgan town council to become members of the Clinical Research Association, Limited, so as to obtain pathological, bacteriological, and chemical examinations at the members' scale of charges. The question of sending patients in the early stages to a sanatorium is to come up for consideration at the next meeting.

Royal Victoria Hospital, Belfast.

At a specially summoned meeting of the corporation of the Royal Victoria Hospital, Belfast, it was decided on June 9th to repeal a by-law which prevented bequests over £200 being used for the annual revenue of this hospital. In future, there will be two separate financial accounts: in one, all the present accumulated funds and any hereafter specially ear-marked for any specific purpose will be kept, and these funds cannot be employed for the annual expenditure, unless by a special vote of the whole corporation; the second account will in future consist of all donations and bequests not specially reserved, and these can be utilised for the annual upkeep of the hospital. The reason for making this alteration is that there are still 64 beds unoccupied owing to funds being wanted, and owing to the pressing and increasing number of patients demanding admission it is felt some effort must be made to meet the difficult situation.

The Belfast Board of Guardians.

Mr. J. S. Bryars, who for the past two years has occupied the position of chairman of the Belfast board of guardians, was accorded a very warm vote of thanks at the annual meeting of his colleagues on June 9th for the extremely efficient and satisfactory way in which he had discharged his duties, and much regret was expressed that he was unable to continue to occupy the chair.

June 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

International Congress of School Hygiene.

THE readers of THE LANCET may be reminded that the Third International Congress of School Hygiene will be held in Paris from August 1st to 26th under the honorary presidency of the Minister of Public Instruction. An exhibition in connexion with the congress will be on view in the Grand Palais in the Champs Elysées. It will include plans and drawings of school buildings and all kinds of materials employed in their construction, exhibits relative to the food, sleeping apartments, and clothing of school children, and sanitary requisites for schools; there will also be sections devoted to the teaching of hygiene in schools, to instruction during and after school age, to schools and classes for backward and defective children, to moral hygiene, and to the hygiene of the teaching staff.

Pupil Midwives and Professional Secrecy.

At a recent meeting of the Society of Legal Medicine M. Thoinot discussed an interesting case which had arisen at a hospital where there was a school for midwives. An unmarried woman had been delivered of a child in presence of the pupils. When a deserted infant was found soon afterwards suspicion fell on her, and the examining magistrate wished that all the pupil midwives should see the deserted infant so that they might, if possible, recognise it. The medical director of the school protested against this, saying that the pupil midwives were present at the delivery in a medical capacity and that they were therefore bound by the rules of professional secrecy, but the magistrates to whom the matter was referred did not share this view. M. Thoinot then resolved to lay the facts before the Society of Legal Medicine, which was unanimously of opinion that the pupil midwives being cognisant of the circumstances in a medical capacity were bound by the rules of professional secrecy.

A Cookery Competition.

On the occasion of the International Cookery Exhibition M. Mesureur, the director of the Assistance Publique, asked the members of the jury to act as judges in a cookery competition arranged by himself, at which prizes were offered to the *chefs* of the Paris hospitals. In the result the gold medal was awarded to the Hôpital Tenon, the names of the hospitals which took prizes of less value, arranged in three classes, being as follows:—(1) Silver-gilt medals: Boucicaut, Hôtel Dieu, Ivry, and Saint Louis; (2) silver medals: Beaujon, Laennec, Maternité, and Pitié; and (3) bronze medals: Bicêtre, Broussais, Cochin, and Salpétrière. If this new departure is followed up and duly supervised there is room for hoping that hospital patients will soon be supplied with food which will be at once wholesome, sustaining, and palatable.

The Sale of Morphine.

An important decision with reference to the sale of morphine has recently been given by the Tenth Chambre Correctionnelle. A pharmaceutical chemist having sold morphine without a medical prescription to a student at Nancy, the latter gave it to one of his comrades, who, as a result of taking it, contracted the morphine habit. The father of the victim then brought an action for damages against the chemist, who, in his defence, said, in the first place, that he was responsible only for his own action but not for the action of the student who had given the morphine to his comrade, and, in the second place, that he had no direct connexion with the injury sustained by the consumer of the morphine. The Lower Court upheld this view, but the higher Tribunal ordered the chemist to pay 100 francs fine and 4000 francs damages on the ground that a pharmaceutical chemist who sells a poisonous substance without a medical prescription knows that he is liable for whatever misuse may be made of it, either by the first recipient or by the next person who comes into possession of it.

The Société de Médecine of Paris.

At a meeting of the Société de Médecine held on June 10th M. de Keating-Hart showed a man who had formerly suffered from cancer of the floor of the mouth with cervical adenitis. After treatment by electrical fulguration he had now remained free from the disease for nearly two years. The interest of the case was increased by the fact that a year ago M. Quenu, on seeing the patient at a meeting of the Surgical Society, expressed the opinion that a relapse was imminent and that the treatment had been a failure. M. Quenu appeared to have been misled by a nodular cicatrix which perhaps resembled a patch of cancer in relapse, but was nevertheless frequently seen in cases treated by fulguration.—M. Dartigues reported a singular case of injury sustained in a recent duel. A pistol bullet of 12 millimetres diameter fired at a distance of 16 metres pierced the trouser of the person struck, but carried before it to a depth of 8 centimetres the corresponding portion of his silk drawers, the silk material being invaginated like the finger of a glove. In its course the bullet divided the internal saphenous vein. Three similar cases were recorded by Baron Larrey, surgeon to the armies of the First Empire.

June 14th.

ITALY.

(FROM OUR OWN CORRESPONDENTS.)

The Fight against Malaria.

"THE fight over malaria" might for the present replace the above rubric, as there is war in the very camp itself where there should be nothing but concord and settled strategy against the common foe. The pitched battle in the Royal Medical Academy of Rome, where the Dean of Italian Medicine came into open conflict with the overwhelming majority of his colleagues, has had its repercussion in the Chamber of Deputies, where, in a debate on the budget of the Minister of the Interior, the etiology, prevention, and cure of malaria rose again to the front. The protagonist this time was the professor of pathology in the University of Naples, Dr. Nicola Badaloni, who, in a speech of great ability, reopened the entire question, and while strenuously vindicating the Consiglio Superiore di Sanità and loyally supporting the State policy inspired by it in the provision, distribution, and exhibition of quinine therapeutically, if not prophylactically, wound up with a demonstration that, however vigilantly antagonised by treatment, malaria will remain a "constant quantity" so long as agriculture in its most scientific and thoroughgoing sense is neglected. This brought up the Dean of Italian Medicine aforesaid (Dr. Baccelli), who gave his unqualified adhesion to the position of Dr. Badaloni, insisting again on the *causa causans* of malaria as residing in the derelict or deteriorated soil, and seeing in hydraulic measures (*inter alia*) the true *modus operandi* in combating it. He then launched into what was really a clinical lecture on the action of quinine on the malaria-infected organism, maintaining that only when the malaria poison was present in the circulation had the drug any germicidal virtue, and that, on the contrary, exhibited by way of prophylaxis to the healthy subject, it was not only inert, but a veritable poison to the vaso-motor system. So far the fight, as between the Royal Medical Academy and its most authoritative member; but a third passage at arms has also been in progress between Dr. Grassi, professor of comparative anatomy and entomology at the Sapienza, and Dr. Bignami, author of the "order of the day," carried, in spite of Dr. Baccelli, by the Medical Academy itself. Dr. Grassi, in very able letters to the *Tribuna*, maintains that the wire-netting as a medium for keeping the anopheles at bay had been unworthily ignored, and replies at length to objections taken to the protective apparatus referred to. Till the "radical cure" is a *fait accompli* we must, he concludes, at whatever sacrifice, employ "mechanical protection," and meanwhile admit the fact, theoretically and practically, that "the prophylaxis by quinine ingested in small doses for many months in succession and repeated year by year *usque ad mortem* on entire populations, is a veritable Utopia." And thus the "pretty quarrel" is being fought out, while, in the words of not the least able of the combatants, the reclamation of the soil, steadily progressing, combines with the prompt and effective exhibition of quinine undoubtedly to lessen the mortality from malaria among the 8,000,000 of Italians in the regions where it is endemic.

Food Poisoning.

In one of the stages of the recent bicycling match round Italy three of the competitors on alighting at Teramo and partaking of refreshment were seized with violent abdominal pains, the chief sufferer being the winner (as he ultimately proved), Signor Ganna. At once the suspicion arose that there had been foul play, a suspicion always likely to obtain credence when "there is money on the game." Dr. Lorenzo Paris, however, writing from Teramo, where he saw the bicyclists as patients, excludes the idea of "foul play" and while admitting that the tomatoes consumed (possibly tinned) may have induced the symptoms, finds concurrent causes in the violent exertion, the checked perspiration, and the excitement. In any case the patients were fit enough to continue their course, and the chief sufferer (as stated) to come home the winner. At Ravenna, however, a far more serious incident of the kind occurred. Ice-cream purveyed by a well-known confectioner and consumed by some 400 persons, mostly children, was followed by undoubted symptoms of poisoning—abdominal inflation, high temperature, and pain diffused over the body reaching its maximum in the chylo-poietic viscera. Two of the victims died, other four were last reported as *in extremis*, while the others are still suffering, more or less severely. Expert examination of the ices disclosed the fact that the eggs employed in their preparation were in an advanced stage of decomposition, and that the poisoning they induced was of the ptomaine order. Two of the waiters on duty at the confectioner's have been arrested. The incident, occurring at the beginning of the season, when the consumption of ices is universal and on an inordinate scale, has produced an impression which, it is hoped, will not be thrown away on the purveyors of ices and the sanitary officers charged with their surveillance.

New Law affecting Foreign Practice in Italy.

The question of the foreign practitioner in Italy, which for so many years has agitated medical circles in this country, has now been settled in what appears to be a fair and satisfactory manner by the Bill which has lately been passed by the Chamber of Deputies. Approved a year ago by the Senate, this Bill, on account of the fall of the Giolitti Ministry, has only now reached the Lower House and been placed upon the statute book, under the title of "Sugli Ordini dei Sanitari." The object of the Bill as described by its promoter, Signor Giolitti, is the institution of organised bodies for the legal representation of the sanitary classes similar to those already existing for the members of the legal profession. There was at first some idea of uniting the medical profession with veterinary surgeons and pharmacists for this purpose, but this proposal had to be abandoned as, for obvious reasons, impracticable, and provision made for a separate organisation for each of the three categories.

Article 1 of the new law therefore provides for the institution of an "Ordine dei Sanitari" in each province of the kingdom for each of the three classes above mentioned. This will be accomplished by means of a register for each category, in which the names of all belonging to that category must be inscribed.

According to Article 2, the enjoyment of civil and political rights and the possession of a professional diploma granted by a recognised institution of the kingdom are the qualifications necessary for registration. To this rule there are certain exceptions. The first regards women with civil rights who have taken a professional diploma entitling them to practise and whom it would therefore be illogical to exclude merely because of their political disability. The same consideration holds good for foreigners who have civil rights and have taken a professional diploma in a competent institution of the kingdom. A third exception is made in favour of citizens and foreigners who have taken a professional diploma abroad. But in this case registration is permitted only to the possessors of foreign diplomas from universities in those states which grant reciprocal rights to diplomates of Italian universities. To obviate injustice being done to foreign practitioners settled in Italy under the old law, Article 10, however, authorises such persons to continue provisionally the exercise of their profession, but only amongst foreigners, and only on condition that for more than two years before the promulgation of the new law they have been enrolled on the list of tax-payers paying taxes on their professional income.

Article 3 makes inscription on the provincial register the *conditio sine quâ non* for the unrestricted exercise of the profession in the kingdom and in its colonies and protectorates, except in the case of sanitary officials connected with the public administration of the State, or of the provinces, or of the communes, and who do not engage in private practice. Such officials are only subject to the discipline of the "Ordine" in so far as may concern their private practice.

By Article 4 no one is permitted to inscribe contemporaneously in more than one provincial register, but his name may be transferred from one register to another under certain conditions.

Article 5 limits the registration fee to a maximum of 25 lire (£1).

Article 6 regulates the election of an executive council for each provincial "Ordine."

Article 7 defines the duties, functions, and disciplinary powers of these executive councils. *Inter alia* they are empowered when requested to intervene in disputes between members, or between a member and his client in regard to charges, fees, or other professional questions, to repress abuses, and to punish those guilty of unprofessional conduct.

Articles 8 and 9 refer to appeals from the "Ordini" and their councils and to various details of administration.

As will be seen, the position of foreign practitioners is considerably affected by the new law. Up to the present, the possession of a diploma from any recognised foreign medical school has been sufficient to secure all the privileges the foreign practitioner wanted—namely, the right to practise amongst foreigners. Henceforward, only those whose respective countries grant reciprocity of medical practice to Italy will be admitted to exercise their profession there. As at the present moment Britain is the only foreign country which has conceded such reciprocity,[1] British practitioners are the only ones whose foreign diplomas can gain them admission to the Italian register. The new law, therefore, affects the British practitioner in Italy favourably, since it gives him complete freedom to practise amongst Italians as well as amongst foreigners. Other foreign practitioners will be variously affected. None of them will be entitled to practise amongst Italians unless they possess an Italian diploma, but those already established and who have been enrolled for more than two years as contributories to the tax on professional incomes will, for the present at all events, be allowed to continue the exercise of their profession, although only amongst foreigners. Finally, all eligible foreign practitioners must become members of the new "Ordini," or associations of the provinces in which they practise, and consequently become subject to the discipline of these "Ordini." Altogether, the new regulations must be acknowledged to be equitable and just, even by those—and they are very few in number—on whom they fall most heavily. New arrivals, indeed, possessing diplomas of countries which do not grant reciprocity to Italy will be excluded henceforth from practice, but even to these it remains open to qualify themselves by taking an Italian degree, which is still obtainable under comparatively easy conditions.

June 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The late Professor Robert Koch.

IN accordance with his testamentary instructions the funeral of the late Professor Robert Koch was conducted with great simplicity. The remains were cremated on May 30th in the crematorium at Baden-Baden, without any previous announcement, not even his friends being informed of the hour at which the event would take place. Besides the widow the only persons present were Professor Gaffky, his successor in the directorship of the Institution for Infectious Diseases, and the deans of the medical faculties of the neighbouring universities of Strasburg and Heidelberg. The deans had come to express condolence on behalf of their faculties to the widow and happened to arrive at the time of the cremation. The *Deutsche Medizinische Wochenschrift* has published an account of Professor Koch's illness written by his medical attendants, Professor Kraus and Professor Brieger. They state that the deceased had for years had an intermittent pulse and that slight symptoms dependent on cardiac stenosis had developed since last March; he had never been addicted to excessive smoking, but repeated attacks of malaria and an attack of cholera had weakened him. During his long journeys through Africa, Asia, and America he had always felt perfectly well. On the night of April 9th in the present year he had a severe attack of angina pectoris which nearly carried him off and made it very probable that he suffered from sclerosis of the coronary arteries and myomalacia of the heart. Pulmonary œdema and passive congestion in the liver and kidneys with albuminuria were present, but disappeared on the administration of digitalis, caffeine, and morphine. A complete recovery, however, did not occur, dyspnœa and pulmonary œdema developing after every slight bodily exertion. He was, however, able to take carriage exercise several times after May 14th, to receive the visits of friends, and to dictate letters. He was perfectly aware of the seriousness of his condition and at the beginning of his illness he had predicted that the end would come in from three to eight days. His medical attendants were subsequently able to persuade him that the dyspnœa was partly due to an old tuberculous focus in his lungs, and it is remarkable that he was then perfectly satisfied because he was not the least afraid of tuberculosis. About a week previous to his death he was taken to Baden-Baden at his own special desire but against the advice of his medical attendants; he arrived there feeling tolerably well, but the symptoms of cardiac stenosis soon became more frequent and finally proved fatal.

Death of Professor Curschmann.

Within a comparatively short period the medical profession of Germany has lost three eminent members, the deaths of Professor Koch of Berlin and Professor Lenhartz of Hamburg being now followed by that of Professor Curschmann of Leipsic. Professor Curschmann was born in 1846 in Giessen, his father being a teacher in a public school. He studied medicine at the university of his native town, and after becoming qualified he acted as house physician at the Rochus Hospital in Mayence. From Mayence he came to Berlin as an assistant to that distinguished clinical teacher, the late Professor Traube; in 1875 he obtained recognition as a *privat-docent* and was appointed chief physician to the Moabit Hospital in Berlin. From Berlin he removed to Hamburg, where he was chief physician to the State Hospital till 1888, when he was appointed ordinary professor of clinical medicine and director of the medical clinic at Leipsic in succession to the late Professor Wagner. Professor Curschmann was an excellent teacher and an eminent therapeutist. He devoted great attention to the improvement of therapeutical methods. In addition to important treatises on typhoid fever, on small-pox, on enteric fever, and on the functional troubles of the genital organs he wrote numerous articles in many different branches of clinical medicine.

June 13th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE statement of plague for the week ending April 16th shows for the whole of India a mortality of 20,365, as compared with 23,988 in the previous week. The deaths in the different provinces were as follows: Bombay Presidency, 709; Bengal, 1439; the United Provinces, 4753; the Punjab, 10,916; Burma, 293; the Central Provinces, 198; and Rajputana, 1890. The worst areas in the United Provinces during the week under review were: Unao District, 351; Gorakhpur, 318; Muttra, 609; Benares District, 399; and Badaun, 250.

The Health of the United Provinces.

It is strongly to be hoped that the next published report on the municipal administration of the United Provinces will be able to record some effective coöperation on the part of the municipal boards in the serious efforts which have lately been made for the improvement of the public health. In 1908–09, as compared with the previous year, the total number of births registered declined from 124,500 to 108,360, whilst that of deaths rose from 145,888 to 148,447. During the year in question, while the general excess of deaths over births attained the deplorable rate of 12·93 per 1000 of the population, this figure was considerably exceeded in some of the towns, while 23 municipalities, situated for the most part in the Meerut, Agra, and Rohilkhand divisions, returned death-rates of 60 per 1000 or over. Malarial fever may no doubt be cited as the main cause of this high proportion, since the epidemic of that autumn was admittedly devastating in its effects. Some further reason is presumably required to account for the appalling infant mortality of the year,

[1] *Vide* Order in Council of March 9th, 1901, published in the London Gazette of March 19th, 1901, putting in force the second part of the Medical Act, 1886, in favour of Italy.

amounting to a rate of 352·93. Since the publication of the last report, however, effect has been given, as circumstances have allowed, to a number of the recommendations of the sanitary conference convened by the Lieutenant-Governor to consider in detail the improvement in conditions, while the special aspect of infant mortality will by now have benefited by the researches of the female staff appointed to investigate its causes at Cawnpore. Investigation has also been proceeding into the causes of malarial fever in the province. But there can be no doubt that the great advance to be looked for must be in the direction of municipal self-help and a ready effort on the part of the boards to give effect to the recommendations of the sanitary officers and to take swift action in accordance with the inspection notes. But if such had been the attitude of the local authorities last year in such municipalities as those of Kandhla, Kurja, Jalesar, and Brindaban, it is certain that the returns connected with their names would not have afforded such regrettable reading.

The Sanitation of Lahore.

The Punjab Government only recently gave the municipal committee the services of a duly qualified health officer, and from the report of that officer for the quarter ending Dec. 31st, 1909, it is clear that there is much room for improvement. Dr. J. L. Newell says that the question of the conservancy of the city and the civil station has received his attention ever since he took over charge of his duties. Many irregularities, he says, have been removed, but he regrets to state that "the conservancy must be considered unsatisfactory." He thinks that the time has come when the committee should definitely decide to hand over the control of the conservancy arrangements to the health officer, as unless this is done efficiency cannot be restored. Conservancy is a technical subject, and it would be wise to leave it to the health officer. We wonder if the attention of Dr. Newell has been directed to that unspeakable nuisance—the conservancy cart, which may be seen "wending its slow length along" even at midday on some of the most frequented roads in the civil station. According to the health officer, the state of affairs regarding the supply of milk is highly unsatisfactory. He hopes, however, that milk licences, at present under consideration, will bring about a much needed change for the better. The report also refers to the need for improvement in the slaughter-house and the meat market.

April 23rd.

Obituary.

WILLIAM HENRY SPENCER, M.A., M.D. CANTAB., M.R.C.P. LOND.,

FORMERLY CONSULTING PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

Dr. William Henry Spencer died at his residence, 8, Asberton-road, Oxford, on May 27th, in his seventy-third year. The deceased was educated at the University of Cambridge and St. Mary's Hospital, London. He graduated M.A. of Cambridge in 1866, M.B. in 1872, M.D. in 1878, and in 1888 obtained the M.R.C.P. Lond. Dr. Spencer was for some years senior physician to the Bristol Royal Infirmary, while he also lectured on the practice of medicine and on pathology at the Bristol Medical School from 1874 to 1888. Amongst his contributions to the literature of medicine are "Elements of Qualitative Chemical Analysis"; and "The Tendency of Disease to Cause Disease, illustrated by the Pathology of Diseases of the Heart and Lungs." He was a thoroughly learned physician.

ARTHUR JOHN SHARP, M.D. LOND., F.R.C.S. ENG., D.P.H. CAMB.

THE medical profession has lost in Dr. Arthur John Sharp, whose premature death occurred on June 6th at Nottingham, a physician of considerable performance and of very great promise. He was the younger son of the Rev. John Sharp, and was born on Dec. 23rd, 1867, at Masulipatam, in South India, where his father was at the time principal of the Church Missionary Society's College. His mother was a daughter of the late Dr. Lachlan MacLean of Oban, and it is interesting to note how very closely Dr. Sharp was connected to the medical profession through his relatives. Among the well-known medical men to whom his family was related were the two William Heys of Leeds and William Sharp of Bradford, who died in that town in 1832.

From 1872 to 1878 Arthur Sharp lived at Rugby under the care of his grandfather (yet another medical man), the late Dr. William Sharp, F.R.S. From Mostyn House School, Parkgate, where he studied, he gained two scholarships simultaneously at Marlborough College, and in due course distinguished himself there. At the close of his school career he gained a scholarship at Lincoln College, Oxford, but surrendered it to study medicine at Guy's Hospital. Here he was a successful student and subsequently, having graduated in 1892 as M.B. Lond., held the posts of resident obstetrician, assistant house surgeon, and assistant house physician. He also acted as clinical assistant at the Evelina Hospital for Children. In 1893 he qualified as M.R.C.S. Eng., L.R.C.P. Lond., and in the following year took his M.D. degree. Two years later he took the D.P.H. at Cambridge and proceeded also to the Fellowship of the Royal College of Surgeons of England.

He practised at Whitby for eight years, and in May, 1898, married the eldest daughter of the late Dr. S. H. Ramsbotham of Leeds. He moved from Whitby to Nottingham five years ago for family reasons. Dr. Sharp was a life member of the St. John Ambulance Association and honorary corresponding secretary to the Nottingham Medico-Chirurgical Society. He held the appointment of assistant medical officer to the Sheffield education authorities, but never acted in this capacity, as the post was given to him during the course of his long illness in the hope of his recovery. Amongst his numerous contributions to various medical journals are "Puerperal Fever Successfully Treated with Antistreptococcic Serum," "Perityphlitis and Life Assurance," "Notification of Births Act," and a serial communication which appeared in the *Guy's Hospital Gazette* entitled "The Scientific Diagnosis of Nervous Diseases."

Dr. Sharp was devoted to his profession, but his interests were not confined to it alone. He was a keen student of English history and architecture. He was president of the Church of England Men's Society at Nottingham, and at the request of this society a memorial service to mark the high esteem in which he was held by all its members took place in St. Nicholas Church on June 10th simultaneously with the funeral at Ambleside, where the service was conducted by his brother-in-law, the Rev. A. Ramsbotham, M.A., vicar of New Seaham. By his own request the remains were interred in the grave of his grandmother (Mrs. Sharp). Dr. Sharp died from the effects of septicæmia which he contracted during the performance of a post-mortem examination over six years ago. He was ill with typhoid fever at the time of the necropsy, and had he relinquished his duties sooner it is possible that the medical profession would not now be mourning his loss.

FRANCIS EDWARD CANE, L.R.C.P. & S. EDIN., D.P.H. CAMB.

WE regret to chronicle the death of Francis Edward Cane, divisional surgeon of the metropolitan police for the Edmonton district, at the age of 55 years. Born in Kilkenny, the son of Alderman Robert Cane, M.D., he was educated in Dublin and afterwards at St. Mary's College and Stoneyhurst. His medical studies were pursued at the Edinburgh School, where he obtained the diplomas of the joint colleges in 1881, and later in London at St. Bartholomew's Hospital. After serving for some time as resident medical officer at the Bradford Infirmary he spent several years acting as medical assistant to practitioners in various parts of the country, acquiring in this way a large amount of professional experience. For a short time he practised in Leeds, but for health reasons he gave this up and accepted the appointment of ship surgeon in the service of the Cunard line. For about eight years he remained at sea, and after carrying on a medical practice for a brief period in America, at Boston, he returned to England, and finally established himself in general practice at Edmonton, where his kindness of heart, his keen sense of humour, as well as his simplicity and straightforwardness of character, soon brought around him a large circle of friends. His varied professional experience and scientific knowledge were quickly recognised, and he had no lack of patients. Some seven years ago he married an

American lady, Miss Helen M. Carter of Boston, who is left with two young children to mourn their loss.

Mr. Cane was an exceptionally well-read man and inherited from his father decided literary tastes. He contributed articles frequently to the general press as well as to technical journals, such as the *English Mechanic*. He took a great interest in astronomy and wrote with some authority on meteors. His medical contributions were somewhat varied in character and showed a wide range of knowledge. His article on the Physiology of Dreams, published in the columns of THE LANCET in 1889, is an example of his versatility. His long experience of life at sea had given him a keen interest in the condition of seamen, more especially as regards their fitness for duty. In this connexion he published articles in the medical periodicals on the Hearing of Seamen and on Colour and Vision Tests for Seamen. He took no part in local politics, though he was asked on more than one occasion to stand as a candidate for the urban district council of Edmonton.

Mr. Cane's funeral took place on May 27th, the coffin being carried to the grave by members of the metropolitan police, a large contingent of the Edmonton Division being included among the mourners. His only surviving brother, Colonel R. Cane, R.A., owing to ill health, was unable to be present. The universal respect and esteem in which Mr. Cane was held in the locality were shown by the large and sympathetic crowds which assembled in the streets to witness the funeral procession passing on its way to the cemetery.

JOHN EUGENE ADOLPHUS CHATELIER, M.B., C.M. EDIN.

WE regret to have to announce the death of Dr. John Eugene Adolphus Chatelier, the senior medical superintendent at the City Hospital, Birmingham, which occurred on June 9th. He was born in Madras in 1867. He spent three years in the study of medicine at the Madras College, and completed his studies in Edinburgh, where he graduated in 1893. Shortly after this he was appointed assistant medical officer to the City Hospital in Birmingham, but after a few months he gave up this position to become medical superintendent to the Little Bromwich Small-pox Hospital. Subsequently he returned to the City Hospital, where his special charge was the fever wing. His death is regretted by the many friends to whom his personal qualities of sympathy have endeared him, and inflicts a serious loss on the public health committee of Birmingham.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Howard H. Barker, formerly professor of midwifery and gynæcology in Georgetown University, Washington.—Dr. Scherb of the Algiers School of Medicine.—Dr. Josef Grünfeld of the Vienna Polyclinic. His name is known in connexion with the endoscopy of the bladder and urethra.

THE BRITISH ANTARCTIC EXPEDITION, 1910.—In connexion with the announcement of the departure of the *Terra Nova* from the West India Docks on June 1st, we are informed that the entire medical equipment and all photographic chemicals for the expedition were supplied by Messrs. Burroughs, Wellcome, and Co.

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of the Royal Sanitary Institute will be held in Dublin on June 24th and 25th. On the first day, at 8 P.M., in Trinity College, discussions will take place on "The Water-supply of Irish Towns," to be opened by Mr. J. H. Swiney, M.Inst.C.E., and on "The Bacteriological Standards of Potable Water," to be opened by Dr. E. J. McWeeney, professor of pathology and bacteriology in the University College, Dublin. Colonel J. Lane Notter, R.A.M.C., will preside, and a general discussion is invited. On June 25th there will be a demonstration at the Dublin Metal Joining Company, where tea will be provided. Further particulars can be obtained from the secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London. Mr. W. Kaye-Parry, M.Inst.C.E., 48, Kildare-street, Dublin, is the local honorary secretary.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the Royal College of Surgeons of England, held on June 9th, the diploma of Fellow was conferred upon the following gentlemen who passed the examination held on May 19th, 23rd, 24th, 25th, 26th, and 27th, for which 65 candidates presented themselves, 24 of whom were approved (including two candidates—P. B. Bharucha, L.M. and S. Bombay, M.R.C.S., L.R.C.P., and Walter Burford Johnson, M.B., B.S. Lond., M.R.C.S., L.R.C.P.,—who have not yet attained the age of 25 years), and 41 were referred:—

Campbell Dykes, Captain, I.M.S., M.B. Lond., M.R.C.S., L.R.C.P., University College and London Hospitals; Thomas Shepherd Novis, Captain, I.M.S., M.R.C.S., L.R.C.P., London Hospital; Thomas John Carey Evans, Lieutenant I.M.S., M.R.C.S., L.R.C.P., Glasgow University, London and St. Bartholomew's Hospitals; Evelyn Henry Bardens Oram, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. George's and St. Bartholomew's Hospitals; Andrew John Metford Wright, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Bristol University and London, Hospital; Lorima John Austin, B.A., M.B., B.C. Cantab., M.R.C.S. L.R.C.P., Cambridge University and London Hospital; Basil Thorn Lang, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Kenelm Hutchinson Digby, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hospital; Walter Bristow Griffin, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Harold Fitz Vellacott, M.R.C.S., L.R.C.P., London Hospital; William Archibald Campbell, M.B., Ch.B. Glasg., M.R.C.S., L.R.C.P., Glasgow University and London Hospital; David Davies, M.R.C.S., L.R.C.P., London Hospital; William Robert Douglas, M.B., Ch.B. Vict., M.R.C.S., L.R.C.P., Manchester University; Philip Seston Vickerman, M.B., Ch.B. Edin., M.R.C.S., L.R.C.P., Edinburgh University; Alan MacDonald Dick, Lieutenant, I.M.S., M.B., Ch.B. Edin., M.R.C.S., L.R.C.P., Edinburgh University and St. Bartholomew's Hospital; Felipe Guevara-Rojas, M.D. Caracas, M.R.C.S., L.R.C.P., Caracas University and St. Bartholomew's Hospital; Cecil Augustus Joll, M.B., B.S., B.Sc. Lond., M.R.C.S., L.R.C.P., L.D.S. Eng., Bristol University and University College Hospital; Howard Buck, M.B., Ch.B. Vict., Manchester University and London Hospital; Robert Harold Campbell, M.B., Ch.B. Glasg., Glasgow University and London Hospital; James Eadie, M.B., Ch.B. Glasg., Glasgow University and London Hospital; Robert Jamison, M.B., B.Ch., B.A.O. R.U.I., Queen's College, Belfast, and London Hospital; and George Herbert Ussher, M.D., Ch.B. Edin., L.M. Dub., Edinburgh University and London Hospital.

The Council conferred the diploma of Member upon Arthur Rocyn Jones, Cardiff and University College Hospital, who has now complied with the bye-laws. Licences in Dental Surgery were also conferred upon the undermentioned three gentlemen, who have passed the requisite examinations and have now complied with the by-laws:—

Claude Gray Colyer, Charing Cross and Royal Dental Hospitals; Richard Pittard Davies, Middlesex and National Dental Hospitals; and Richard Gorrall Miller, Charing Cross and Royal Dental Hospitals.

THE Institute of Marine and Tropical Diseases at Hamburg is to be enlarged, and the senate and freemen of Hamburg, recognising the importance and excellence of the work it has already done, have voted £65,000 (1,339,300 marks) to the extension fund. A section of veterinary pathology will find a place in the new buildings.

LIVINGSTONE COLLEGE.—At the Commemoration Day proceedings at Livingstone College on Saturday, June 11th, a reception was held to which a number of foreign delegates, now in England for the World's Missionary Conference at Edinburgh, were invited. The Principal, Dr. C. F. Harford, after welcoming the guests, spoke of the aims of Livingstone College. He emphasised the necessity of a medical training for those who go abroad as missionaries, not only for the care of their own personal health, but to enable them to treat the natives amongst whom they work. He drew attention to the importance of the training at Livingstone College as enabling students to acquire some knowledge of tropical diseases. He then proceeded to read an address which had been specially written for the occasion by Professor Ronald Ross, who was unfortunately unable to be present. In this address reference was made to the remarkable development of science in connexion with malaria during the past decade, and to the necessity for medical missionaries adopting systematic measures against the spread of this disease. Professor Ross referred to the various prophylactic measures such as drainage of stagnant waters, removal of water weeds in which mosquitoes live, and treatment of the water by

larvicides or oil. The address concluded with the advice that every missionary going to a tropical country should take a course of study in tropical medicine.

AMONG those called to the Bar at Gray's Inn on June 8th was Dr. J. Malcolm Mason, consulting medical officer to the Dominion of New Zealand.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The distribution of prizes will take place at 17, Bloomsbury-square, London, on June 23rd, at 3 P.M.

THE Directors of the London, Brighton, and South Coast Railway Company have appointed Mr. William Turner, M.S. Lond., F.R.C.S. Eng., medical officer of the company in succession to the late Mr. William Rose.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co. announce for immediate publication a new and enlarged edition of "Difficult Labour," by Dr. George E. Herman. "A Manual of Chemistry" by Dr. A. P. Luff and Mr. Hugh Candy is also about to appear in a new edition.

UNIVERSITY OF CAMBRIDGE.—The Special Board for Medicine of the University of Cambridge has recommended that the degree of M.C. be conferred on Mr. Herbert J. Paterson, M.A., M.B., B.C., F.R.C.S. Eng., of Trinity College, without examination, in consideration of his contributions to the science and art of surgery.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.—A special appeal committee, under the chairmanship of Lord Derby, has been appointed by this association to collect funds for an educational campaign. The movement is intended to familiarise the general public with the various preventive measures which may be adopted against tuberculosis. The association means to organise travelling tuberculosis exhibitions, and to place on the road caravans containing the necessary outfits for lantern exhibitions; and it will also arrange for popular lectures to be delivered, for the institution of a general information bureau for the benefit of the public, and for the distribution of leaflets. The committee states that the total expenses of such a programme as this will amount to nearly £5000 annually, and asks the public for generous support in raising the necessary funds.

CHICHESTER INFIRMARY.—The debt of £1488 existing at the end of the last financial year on the West Sussex, East Hants, and Chichester Infirmary, or, as it is perhaps better known as, the Chichester Infirmary, has now been liquidated by contributions either given or promised, chiefly in answer to the appeal sent out by the mayor of the cathedral city. The late King Edward took a great interest in the West Sussex institution, visiting it during his frequent sojourns in the neighbourhood. During his last visit towards the end of last year His Majesty graciously consented to consider the question of permitting the designation of "Royal" to be used, provided the institution were made free of debt. Sir Frederick Treves, at the late King's suggestion, carefully examined the infirmary and found the interior entirely out of date and its structural condition not creditable to the county. "Medical and surgical science," Sir Frederick Treves said in his report, "has made immense strides in the last 25 years, but this hospital has certainly not moved with the times, since it remains practically as it was some 30 years ago. ..... Its condition is most unsatisfactory. Full justice cannot be done to the patients on the one hand, nor to the medical staff on the other. The work done by the staff has been admirable, but it has been done under conditions which ought not to exist in these days, and in the face of difficulties with which they should not be hampered." Sir Frederick Treves strongly advised an extensive reconstruction to convert the building into a modern hospital and to bring it in line with the other hospitals of like standing in the country. It is now proposed to bring the hospital thoroughly up to date at a cost of £20,000 as a memorial to King Edward. Although this proposal is quite in its infancy one-half of the sum required has been promised by an anonymous donor. The Chichester Infirmary can date back as far as 1792, when it commenced its work in a small house with one nurse. Now in the course of one year it admits 124 medical cases, treats 445 surgical cases, relieves 1990 out-patients, and performs 522 major operations.

THE honorary degree of D.Sc. has been conferred on Professor W. Osler, M.D., F.R.S., by the University of Leeds.

Professor and Mrs. Karl Pearson and the staff of the Biometric and Galton Eugenics Laboratories are holding an At Home on Friday evening, June 24th, at University College, Gower-street, when the laboratories will be open to their visitors.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The dates of the Professional and Gaskell Prize Examinations have been altered as follows: Professional Examination, July 6th, to be held in London, Edinburgh, and Dublin; Gaskell Prize Examination, July 7th, to be held in London only. The egistrar is Dr. Alfred Miller, Hatton Asylum, near Warwick.

EAST SUFFOLK AND IPSWICH HOSPITAL.—The new President of the Ipswich Hospital, Dr. J. H. Bartlet, held a reception on June 11th, to which some 1400 of the subscribers to the Improvement Fund of that institution were invited, in order to inspect the improvements and additions which have recently been made. The alterations took three years to carry out and cost nearly £20,000; they include the erection of a new administrative block, a new operating theatre, an isolation hospital, and various new outbuildings. A cordial vote of thanks was offered to the subscribers who attended the reception by the board of management, and the chairman congratulated Dr. Bartlet on his appointment as President of the institution.

MUNIFICENT GIFT TO A SANATORIUM.—The bi-annual meeting of the Poor Children's Holiday Association and Rescue Agency was held on May 28th in the sanatorium at Stannington, Northumberland. Commenced a few years ago with a view of obtaining a little fresh air for the poor children of the Newcastle-on-Tyne district by means of day trips to the seaside, the work has extended and now includes the management of a sanatorium for tuberculous children, a convalescent home for children after general diseases, and a farm worked by lads in their teens who have been rescued from a street life. The produce of the farm is utilised in the two other buildings, also on the farm land at Stannington, and so excellent are the arrangements that the farm is a concern which pays for itself. As to the more particular medical aspects of the work, the sanatorium for the tuberculous will accommodate 50 children at present. In the course of remarks from the chair at the meeting the Lord Mayor (Sir William Stephenson) stated that it had been considered desirable that the number of beds should be increased to 100; a good many of these beds it was proposed to devote to local tuberculosis in the way of bone and gland affections. This would mean increased expenditure and funds, and he announced then several subscriptions, including the endowment of a cot. The Lord Mayor's words had a splendid sequel. A few days after the above meeting some correspondence was printed in the local press showing that the Lord Mayor had generously offered to defray the whole expense of building and equipping the suggested additional buildings for the beds above mentioned, some £4000 in all. This munificence will doubtless stimulate the public to help in the extra maintenance expense. It is interesting to note that the concrete blocks to be used in the building operations are being made by the boys on the spot.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Reassembling of Parliament.

PARLIAMENT reassembled on Wednesday, June 8th, after the "spring recess." The holidays as originally planned were interrupted by the death of King EDWARD, but the vacation was afterwards prolonged into June with the intention of silencing current political controversies during the first weeks of the new reign.

Midwives Act Amendment Bill.[1]

The following amendments to the Midwives Act Amendment Bill are desired by the Midwives' Institute, which body has approached the late Lord President of the Council, Viscount WOLVERHAMPTON, and has made an eloquent representation of the views indicated by the suggested alterations:—"Clause 1 (1) c.: Read. Two persons, one of whom

[1] See leading article in THE LANCET on p. 1699.

shall be a midwife, to be appointed by the Incorporated Midwives' Institute, and one person to be appointed by the Royal British Nurses' Association. Clause 7, line 29: For 'March' read 'January.' Clause 11 (1): Omit. Clause 11 (2), line 31: For '48 hours' read '7 days.' Clause 13, line 11: After 'training' insert 'and make grants in aid of maintenance.' Clause 15: Omit. Clause 17 (1), line 3: Instead of 'the Board of Guardians of the Poor Law Union' read 'the local supervising authority of the county or county borough.' Clause 17 (2) and (3): Omit."

A Revised Anthrax Order.

The returns made to the Board of Agriculture show an increased number of cases of anthrax. It has been stated in the House of Commons that three persons have died in three weeks from the disease contracted from the carcasses of animals affected with the disease. The Board of Agriculture is therefore considering the issue of a revised Anthrax Order at an early date which will be designed to secure a more uniform and efficient method of diagnosis of the disease amongst animals.

Clinical Chairs at Glasgow.

The Glasgow University Chair of Clinical Medicine and Chair of Clinical Surgery Confirmation Bill and the St. Mungo's College Confirmation Bill have been read a second time in the House of Lords.

The Census.

In the Census of 1911 certain new information is to be collected bearing on the vital statistics of the nation. Mr. BURNS, the President of the Local Government Board, in his speech on the second reading of the Census (Great Britain) Bill, intimated that the authorities concerned were making provision that information should be obtained from married couples as to the duration of marriage, and as to the number of children born of each marriage. Mr. BURNS believed that the figures so furnished would give information to the fertility of different classes of the community, and would have a bearing upon certain questions connected with infantile mortality. He mentioned that since 1851 the birth-rate had dropped from 34 to 26 per 1000, and in the same period there had been a fall in the death-rate from 23 to 15 per 1000. Infantile mortality was practically stationary until five years ago. Since that time the rate had fallen from 145 to 109 in England and Wales, and from 144 to 107 in London.

Experiments on Living Animals.

A return has been ordered by the House of Commons of the experiments made on living animals during the year 1909 under licences granted under 39 & 40 Vict., c. 77, distinguishing the nature of the experiments.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 8TH.

Medical Establishments in the Navy.

The House considered in committee of supply a vote of £263,900 for medical services and medical establishments in the Navy.

Lord CHARLES BERESFORD said that the First Lord of the Admiralty in his annual statement had mentioned that questions of very great importance and far-reaching scope would be brought before the committee which the Admiralty very wisely ordered to investigate affairs connected with the Naval Medical Service. The First Lord had said that he would let the House have the report of the committee as soon as possible, and he (Lord C. Beresford) hoped this would be done. He thought that it was of the highest importance that the Navy Medical Service should be organised and ready for war. Unless surgeons and staff were organised in time of war it would be a matter of very serious consequences. One shell could kill a great number of people and also wound perhaps 60 or 70 men, so a proper medical staff should be quite ready to go on duty if war were suddenly declared. Since the South African war the army had recognised the importance of this point. There was a school at Millbank which prepared medical officers for duties in which they could not otherwise have much practice in case of sudden emergency of war. He hoped that the First Lord of the Admiralty would announce that some sort of naval medical school, something similar to that which had been provided for the army, would be provided for the navy. He found that on the peace establishment as stated in the Navy List there ought to be 574 staff surgeons, and, as far as he could make out, the actual numbers were 60 or 70 short on the peace establishment. That was a very serious position. He hoped that the First Lord would say what his intentions were in regard to it. There were only 34 reserve volunteers on the Navy List. He thought that the number of these volunteers might be increased by inviting the surgeons of mercantile ships to become surgeons for the Royal Navy in reserve. He believed that they would be very glad to do so, and there would be the advantage that these men were accustomed to be at sea. Another point on which he touched was the status of the sisters in the naval hospitals. Since their advent the naval medical hospitals had improved enormously, and the First Lord would do well to put these sisters on terms similar to those given to the sisters in the army service. They ought not to feel that they were underpaid in comparison with the army sisters. The noble lord went on to urge the necessity of building two hospital ships. It was essential that they should be provided in these days when modern weapons and high explosives would produce a tremendous sacrifice of life and inflict a great number of wounds. These ships would perhaps get to the place where they were wanted within a few hours. If hospital ships were properly equipped with stores and a staff with an adequate number of surgeons, hundreds and hundreds of men's lives would be saved. An ordinary merchant ship could not be converted into an efficient hospital ship.

Mr. ASHLEY urged that the remuneration of sisters should be increased. He thought the suggestion of the noble lord that civil surgeons should be retained for medical service in the Navy in time of war was excellent, because the surgeons who were in the merchant service were just the men who would be thrown out of employment when war broke out. They were the very men who were familiar with the sea.

Mr. GIBSON BOWLES admitted that in war-time considerably more surgeons were wanted than were now in the service of the Navy. He did not think that an additional number of surgeons such as would suffice would be obtained from the merchant service. Ships in the merchant service, except the great liners, did not carry surgeons, and they would be required in war-time as well as in peace. He did not agree that in time of war passenger steamers would be stopped from running. Therefore the Admiralty could not look for any great increase in that direction.

Lord CHARLES BERESFORD: I am afraid that I failed to make my remarks clear. What I meant was that those who had already served as surgeons—and there is a very great number—are men I desire to see in the Reserve. Of course, they would only form a part of the large number required.

Mr. GIBSON BOWLES: I follow the noble lord in what he says. The honourable Member went on to say that as a matter of fact medical men who had served for a time in the merchant service generally took a country practice which they would not readily be induced to leave. The suggestion of the noble lord had something in it, but his (Mr. Bowles's) criticism was that very few surgeons could be obtained from that source. He wanted to know what arrangements the Admiralty had already made to increase the number of surgeons in time of war.

Mr. LEE advocated the provision of hospital ships.

Mr. MCKENNA (First Lord of the Admiralty) said that he had carefully listened to the speeches and could not help feeling a certain amount of satisfaction in recognising that every point of criticism that had been raised had, in fact, been dealt with by the committee which inquired into the Medical Service. He regretted that it had not been possible for him to publish even a part of the report before bringing on this vote. He hoped that honourable Members would accept his statement that not a single point which had been raised in the discussion had been overlooked in the inquiry which had taken place. The recommendations of the committee were at this moment engaging the consideration of the Board of Admiralty, and he was not going too far when he said that not only the bulk of them had been accepted but provisions would be made in order that they might be carried into effect. Of course, some points which had been referred to were matters upon which the Admiralty were not the only authority which had to be consulted. He was not now speaking of hospital ships, but when the Admiralty had to deal with questions relating to nurses and the members of the Medical Service and the raising of the standard of existing salaries there was another authority which had to be consulted. Consequently he was not in a position to make any promise upon any such point. But certainly the recommendations of the committee of inquiry would receive from the Board of Admiralty the recognition which they undoubtedly deserved.

Lord CHARLES BERESFORD: Is the increase of salaries a recommendation?

Mr. MCKENNA: I hope the noble lord will not press me as to particular points in the committee's report. It is far better that we should not deal with a part of it, but I hope to be able to give some information shortly. He would remind the noble lord, who referred to the experience gained in the South African war, that Sir Alfred Keogh was a member of the committee of inquiry, which had had the advantage of the experience and knowledge which he had gained in the army. The question of a hospital ship was raised, and he (Mr. McKenna) agreed with the observations of honourable Members upon the superiority of the hospital ship over the converted merchant ship. Here, again, he was not willing to pledge himself as to what the estimates of the ensuing year would be. He could, however, assure honourable Members that it was the present intention of the Board of Admiralty to include a sum in next year's estimates for the building of a hospital ship. He could not undertake that the Board should build two at once, but he hoped next year to make a start and build one. He trusted that when it was built it would give such satisfaction that a second would shortly follow. He believed that he had touched on the various points which had been raised.

The vote was then agreed to.

Reports of School Medical Officers.

Mr. RAMSAY MACDONALD asked the President of the Board of Education whether it was still the intention of the Department to keep as confidential the information derived by the medical officer from the inspection of school children; and if so, whether he had considered the impropriety of allowing authorities to appoint as medical inspectors persons who already held the office of public vaccinator.—Mr. RUNCIMAN wrote in reply: The Board remains at present of opinion that it is desirable that these reports should be regarded as confidential. As regards the second part of the question, I must refer the honourable Member to the answer he received from my right honourable friend on March 9th.

MONDAY, JUNE 13TH.

Malta Fever.

Mr. CHANCELLOR asked the Under Secretary of State for the Colonies whether it had been decided to appoint a new Mediterranean Fever Commission for the purpose of investigating the manner in which goats became infected, seeing that it was officially stated in evidence before the Royal Commission on Vivisection that no goats had been infected by the alleged Malta fever germ, that it did not give rise to any ill-health, and that it did not give rise to any fever; and, seeing that, according to official statistics, Malta fever had been practically extinguished from among the British garrison before the order of July 1st, 1906, for the prohibition of goats' milk was issued, what public ends were sought by spending time and public money in prosecuting a research which appeared to have no bearing whatever upon the question of Mediterranean fever.—Colonel SEELY replied: It has been decided to appoint another Commission for the investigation of the question to which my honourable friend refers. The evidence of Sir David Bruce before the Royal Commission on Vivisection, to which allusion is made, was to the effect that the goats, though their blood and milk contained the micrococcus of Malta fever, and they were therefore capable of infecting man with the disease, remained themselves apparently healthy. Such tolerance of disease germs is, the Secretary of State is advised, a common physiological phenomenon. My honourable friend is mistaken as to the statistics of admissions to hospital among the troops

for Malta fever. In 1905 there were 643 such admissions; up to July, 1906, when the prohibition of the use of goats' milk was issued, there were 123, for the remainder of the year 40; for 1907, 11; 1908, 5; 1909, 1; and 1910 to date, 0. As it is not practicable to prohibit the use of goats' milk among the civil population it remains to investigate the causes of the infection of goats and, if possible, to remove them.

The Notification of Pulmonary Phthisis in Scotland.

Mr. WILLIAM YOUNGER asked the Lord Advocate how many local authorities in Scotland in burghs and counties, respectively, had added pulmonary phthisis to the list of compulsory notifiable diseases under the Infectious Diseases Notification Act, 1889, and how many cases were notified in 1909.—Mr. URE replied: The Local Government Board has approved the orders of 41 burghal local authorities and of 33 landward local authorities extending the provisions of the Act referred to by the honourable Member to pulmonary phthisis. 1902 cases were notified in the year 1909.

TUESDAY, JUNE 14TH.

Emergency Cases under the Midwives Act.

Mr. HENRY WALKER asked the President of the Local Government Board, with reference to the medical man called in on an emergency under the statutory rules, in pursuance of the Midwives Act, and to the fact that payment was now being made to him out of the rates in some places under the Public Health Act, 1875, and in others under the Poor-law Amendment Act, 1848, whether, in the absence of any application for consent by or on behalf of the patient or her husband, such a payment out of the rates to the medical man, whether under the one Act or the other, was treated as parochial relief; whether, as a matter of fact, the patient and her husband in respect of attendance on the former of whom the medical man was thus paid under the Poor-law Amendment Act, 1848, were in some unions, but not in others, entered and classed as paupers in receipt of medical relief; whether, when the payment was made under the Public Health Act, 1875, the patient and her husband were everywhere spared from any demoralising contact with the Poor-law and were not subjected to visits from the relieving officer; what authority in each locality decided whether the payment out of the rates to the medical man should be made under the one Act or the other; what authority determined whether the patient and her husband in those cases in which no application or consent was made by them or on their behalf should or should not be regarded as in receipt of parochial relief and be dealt with as paupers; and whether, in view of the diversity of opinion and of action among local authorities in this matter, he would issue a circular clearing up the legal position.—Mr. BURNS replied: As I informed my honourable friend in answer to his question of April 28th last, there are two or three cases in which payments of the kind referred to have been made under Section 103 of the Public Health Act, 1875. Such payments would not be parochial relief. Some boards of guardians have, I believe, made similar payments under Section 2 of the Poor-law Amendment Act, 1848, but I have no information as to the practice in the matter. It does not seem to me to be necessary to adopt the course suggested in the last part of the question. I may remind my honourable friend that a Bill has been introduced on behalf of the Government in another place which contains a provision on this subject, and I can assure him that the points to which he has drawn attention will not be lost sight of.

Dr. ADDISON: With regard to the Bill introduced by the Lord President of the Council, will he see his way to substitute the local supervising authorities for the boards of guardians?—Mr. BURNS: I have already told my honourable friend that the points to which he has drawn attention will not be lost sight of.

BOOKS, ETC., RECEIVED.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EPILEPTOID EXPLOSIONS.

A TRAIN steams into a central station like that of Milan (writes an Italian correspondent) and from among the crowd of alighting passengers a man, evidently a prey to cerebral commotion, is seen brandishing a knife with lethal intent, and before the railway servants can secure him has already wounded two or more of his fellow-travellers and dealt a mortal blow to a third. In a military centre like that of Pisa a linesman rises in the night and discharges from a loaded rifle that happens to be within reach a succession of shots which cost several of his sleeping comrades their lives. On board a destroyer in Sicilian waters one of the crew develops a sudden antipathy to his superior officers and in answer to an appeal to control himself takes a header into the sea. His brother mariners leap down after him with intent to save him, but their efforts only result in a violent struggle in the waves, the would-be suicide doing his utmost to involve them in the fate he designed for himself, till, with the aid of a rope flung from the ship, he is brought safely on deck and, still violent and aggressive, is landed at Brindisi and taken to the asylum, where he is reduced to impotence in a strait waistcoat. While this is happening on the high seas, in the barracks near Civita Vecchia a common soldier seizes a rifle, discharges it in front of a house, and again at the room where the officers are sitting at mess. No fatal result has yet occurred, but two females, leaning out of a window on hearing the detonations, are at once aimed at by the soldier, who kills one of them and gravely (it was feared mortally) wounds another. By this time two corporals pounce upon him from behind, and, having disarmed and secured him, convey him to the hospital, where he is found to have suffered from melancholia, with an anamnesis of epilepsy, and put under coercion and treatment accordingly. Cases like these may from week to week be culled from the Italian newspapers with such frequency that not only the citizens, but even visitors from abroad, are beginning to ask themselves how far it is safe to venture near a military barrack, or a railway station, or a crowded piazza, where at any moment an "epileptoid explosion" may occur to the danger, often resulting in the death, of the unsuspecting bystander or wayfarer. The truth is that the often-demanded, perfunctorily recognised surveillance over the youth of Italy, whether entering school life or enrolled for military service, has yet to be initiated and systematically carried out on the lines recommended, now these 25 years, by the Subalpine medical authorities, with Lombroso at their head. That able pioneer, notwithstanding all the "defects" (neither few nor small) "of his qualities," struck a sagacious and salutary note when he urged on the cities and communes an early, thorough, and well-organised examination of the children before these were allowed to mingle together in the school-room or the playground, testing them anthropometrically and pathologically, while not losing sight of their family history, and according to the findings thus arrived at by the duly qualified expert segregating the healthy from the unsound and placing the latter under special conditions, so as to give them a fair chance of normal development, while securing the former from the risk of contamination (moral even more than physical) at their hands. The same process, pleads the Subalpine school, should be resumed after the age of puberty or at adolescence, particularly on admitting the recruit to service in the army and navy or the youth in general to any *métier* in which they may be so employed as to come into daily contact with their fellows. Another recommendation from the same source, though admittedly more difficult to give effect to, is the restriction of publications tending to familiarise the young with crime. The imitative instinct, the ready response to suggestion, is too marked a feature in the budding mind (particularly of the less normally developed or constituted) not to make the perusal of the "cronaca nera," as the police reports are called in Italian journals, a truly dangerous practice in youth or even in adult age. These journals, to judge from their tables of contents placarded at every coign of 'vantage, seem to subsist on sensational news, murders, suicides, abductions, frauds, all on a highly pronounced and piquant scale, being apparently the chief attraction for their readers. Even worse are the comic prints, dealing (as is usual in Latin countries) with breach of the conjugal tie or premature indulgence in the marital privilege, prints eagerly scanned by children of tender years at shop windows, and inciting to excesses which explain the appalling prevalence of "malattie celtiche" in Italy with the sequelæ that crop out in the protean forms of disease inherited and acquired—forms conspicuous among which are the "epileptoid" above referred to. Italy is honourably distinguished among countries constitutionally governed by the large number of physicians, surgeons, and sanitarians in her Senate and Chamber of Deputies. Is it too much to expect that she should also distinguish herself by active and effective legislation towards the abatement of evils, physical and social, in which (to use the phrase of one of her professional authorities) she maintains a "sinister priority"?

SCHOOL CHILDREN AND MEDICAL CHARITIES.

AN excellent institution is that adopted every year at Brighton and Hove, where, under the auspices of the Teachers' Association, a collection is made in the various schools on behalf of the local medical charities. Invariably at the time the collection is being made the teachers expound upon the value of the medical charities and the magnificent work they are doing, while the ingathering of the coppers instils upon the minds of the children a sense of duty towards the many medical agencies, a sense which will grow with them. The annual collection at the Brighton and Hove and district this year amounted to just over £145, which sum has been distributed as follows: 20 guineas each to the Sussex County, Children's, Throat and Ear, and Eye Hospitals; 14 guineas to the Brighton Dispensary; 10 guineas each to the Brighton Dispensary (Hove Wards) and the Queen's Nurses; 6 guineas each to the Women's Hospital and the local branch of the Surgical Aid Society; 5 guineas to the Dental Hospital; 4 guineas to the Brighton Dispensary (Lewes-road Ward); 2 guineas to the Sussex Homœopathic Dispensary; and 35*s.* to the Edward-street Medical Mission.

THE MEDICAL LAW-STUDENT.

To the Editor of THE LANCET.

SIR,—"Legal" will not find very great difficulty in reading for the Bar examinations. I accomplished the task a few years ago whilst leading a very busy life professionally and otherwise. In addition to my ordinary professional work, which was very heavy, I was a member of the city council and board of guardians, taking some very responsible positions in both. For a man in active work it is advisable to take the examinations piecemeal. I read without the aid of a correspondence coach; I tried one, but dropped the system at once, as I found it useless. When I was ready for an examination I generally went to London for four or five days previous to the examination day for a thorough revision of the work. During the time I was reading I discarded every other form of recreation; my spare moments were utilised, and working with me had to be continuous, because when a man reaches 40 he finds his brain is not so retentive. I am, Sir, yours faithfully,

Leeds, June 13th, 1910. A. HAWKYARD.

To the Editor of THE LANCET.

SIR,—Having read for and been called to the Bar whilst carrying on a busy general practice, I write to say that it is quite a practicable thing to do. Attendance at lectures is not compulsory (unless there have been any recent regulations on this point), but in the case of the second examination (Constitutional Law and Legal History) such attendance is very advisable, or at least a copy of the lectures as delivered should be obtained from a fellow student; this can easily be done, as the lectures are delivered sufficiently slowly to be easily reported verbatim. No systematic coaching is necessary, but an excellent plan is to get a coach to advise as to the course of reading and to spend an occasional hour with him subsequently, especially as the examinations draw near. The coach will advise as to the special subjects likely to be dealt with in the examinations, and a good deal of unnecessary reading will be thus avoided. I will give your correspondent any other information with pleasure if you care to put him in communication with me. I am, Sir, yours faithfully,

June 15th, 1910. E. S.

CLIMATIC AND OTHER CONDITIONS OF LIBERIA.

IN his annual report to the Foreign Office, just issued as a Parliamentary paper, Mr. M. Y. H. Parks, British Vice-consul in Liberia, the negro republic of West Africa founded by the American Colonisation Society in 1820, observes that the climate is equatorial, but that small as the country is in geographical extent (about 8000 square miles) it has not a uniform climate over its surface. There is a perceptible dry season between December and April, during which vegetation becomes very parched, and some cool nights during this time of the year are not infrequent. Nine months of the year the tendency in the coast lands is towards excessive humidity, with all its consequences of rust and mould, and the drying influence of the Harmattan wind, though so extreme, is scarcely a remedy for so destructive an element. The most unhealthy months appear to be September and October, nearing the end of the rainy season, which commences in May. The average temperature may be said to range on the coast from about 74° at 6 A.M. to 88° at noon. The average annual rainfall is about 150 inches. Owing to the want of sanitation, the difficulty of obtaining fresh food, and the extreme humidity, the climate is, apart from the prevalence of malarial fever, both enervating and dangerous to Europeans, though they could, no doubt, with annual trips to cooler and healthier climes, live in the country for some years provided they were always moderate in their manner of living. There are no reliable statistics as to population, but there are believed to be from 1,500,000 to 2,000,000 natives. The British population of white people numbers only about 50 persons, mostly males. English is the official and recognised language of the country, but there are, of course, many native dialects. Transport facilities are of the most primitive kind. There are no railways and all transport is done by native carriers. There are no roads in the country, but the interior is intersected by numerous tracts, some of which are barely a foot wide. Many medicinal plants growing in an uncultivated state are made use of by the natives, as well as by the Liberians, for domestic purposes, and a few varieties have found their way to foreign markets, where they have been proved to be of good commercial value. There are no druggists' or chemists' stores in Liberia, and the people depend upon their private supplies imported from Europe; further, there are no hospitals or dispensaries to create a demand for such goods. The only European medical practitioner is the Government medical officer, who is allowed to carry on private practice so far as it does not interfere with his official duties.

THE LUNACY FEES AND THE RESIDENT MEDICAL OFFICER.

WE published a letter in our last week's issue, signed "M.B., C.M. Edin.," under this heading in which exception was taken to the fact that the Board of Guardians of the Poor of the Parish of St. Giles, Camberwell, now directs that lunacy fees in excess of £60 per annum should be repaid to it by its resident medical officer at the Constance-road Workhouse. This week another correspondent sends us a copy of the application form for this appointment. In this document it is shown that in addition to the £200 salary, lunacy fees up to a total of £60 per annum are paid "after the rate of £15 per quarter, provided that the fees in respect of such a period amount to that sum." Our correspondent draws attention to the fact that the resident medical officer may get less than £60 from the lunacy fees, even while the guardians are saving more than £100. He says that at the Constance-road Workhouse from 200 to 300 cases of lunacy pass through the workhouse yearly, but the fees might none the less amount to less than £15 in one quarter, while they came to a much larger total in other quarters. We do not know if the guardians have planned the quarterly payments in this way, but if the circumstances are correctly stated it does not seem a very straightforward arrangement. Guardians must not, however, be blamed for economy if their economy is attended by fair treatment of employees.

POST-GRADUATE WORK IN VIENNA.

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me where I can get information relating to post-graduate work in Vienna, fees, and cost of living?

Yours truly,

June 13th, 1910. LEICESTERSHIRE.

*** Vide THE LANCET, June 11th, 1910, p. 1621.—ED. L.

"WISE WOMEN" OF ANCIENT IRELAND.

IT appears that the "wise woman" is still to be found by those who know where to search among the Somersetshire and Devon peasants. She is probably of Celtic origin. In Camden's "Britannia" is a curious account of the manners and customs of the Irish of the time of Queen Elizabeth, who, under the designation of "Wild Irish" or "Mere Irish," were a constant source of bewilderment to our ancestors. We read in this description, for the facts of which Camden professed himself indebted to Good, a Limerick schoolmaster in holy orders, educated originally at Oxford, that the Celtic Irish think that witches "have peculiar charms for all evils, shared and distributed among them; and therefore they use them according to their several gifts and endowments. They begin and conclude their incantations with a Pater Noster and Ave Maria. When any gets a fall, he springs up, and turning about three times to the right, diggs a hole in the ground with his knife or sword, and cuts out a turf; for they imagine there is a spirit in the earth. So that in case he grows sick within two or three days after, they send one of their skill'd women to the place, where she says, I call thee P. [a person not specified] from the east, west, south and north, from the groves, the woods, the rivers, the fens, from the fairies, red, black, white, &c. And after some short ejaculations, she returns home to the sick person, to see whether it be the disease Esane (which they imagine is inflicted by the fairies), and whispers into his ear a short prayer and a Pater Noster; after which she puts some coals into a pot of clear water, and then passes a better judgment upon the distemper than many Physicians can do." The modern "wise women" seem to have lost their skill in diagnosis.

METEOROLOGICAL CONNEXIONS.

AT the monthly meeting of the Royal Meteorological Society on Wednesday afternoon last, a paper was read from Mr. J. I. Craig, of the Egyptian Survey Department, Cairo, entitled "England, Abyssinia, the South Atlantic; a Meteorological Triangle." The idea that there may be an organic connexion between the annual or seasonal total of rainfall in Western Europe and the amount of the Nile flood is no new one, for in 1882 Professor Balfour Stewart gave reasons for claiming such a connexion between the flood of the Nile and the flow in the Thames. More recently Colonel H. E. Rawson has indicated a connexion between the weather in South Africa and that in Africa north of the Equator, and in particular the Nile flood. Dr. G. T. Walker has found a connexion between the monsoon rainfall in India and pressure six months previously in Argentina and Sir Norman Lockyer has proved the existence of an inverse barometric relationship between India and Argentina. Dr. W. N. Shaw has also drawn attention to certain correspondences between the velocity of the wind at

St. Helena and the intensity of rainfall in the South of England, and pointed out that in the steady current of the south-east trade-wind we may expect to find evidence of the throbbing of the aerial pulse consequent on the greater or smaller supply of solar radiation that reaches the earth and is transformed into kinetic energy. Within the last few years an organised meteorological service has been started in Egypt, and the results obtained therefrom have enabled Mr. Craig to carry out this investigation more closely. He finds that there is a distinct tendency for the south-east trade-wind of the South Atlantic to divide into two branches, the first continuing the general northward movement, and the second turning to the right and moving across into the interior of Africa. He concludes that the moisture for the Nile flood comes from the South Atlantic and that an increase in the velocity of the current will show itself in a proportional increase of the flood. There are too many gaps in the velocity records for the summer months to allow of a statistical test being applied, but it is not improbable that an intensification of the trans-African current is connected with a similar intensification of the south-east trade-wind of the Atlantic, which, as Dr. Shaw has shown, is not improbably connected with an increase of rainfall in the South of England.

A WARNING.

To the Editor of THE LANCET.

SIR,—I wish to warn your readers that a man is going about the West-End saying he has been injured by falling over a loose coal-cellar plate in the pavement, and claiming damages for loss of work. I shall be glad to know if any others have been made the subject of a similar attempt at blackmail. If so, prompt measures must be taken against this kind of fraud.

I am, Sir, yours faithfully,

ONE WHO DOES NOT INTEND TO BE VICTIMISED.

June 14th, 1910.

NAUHEIM BATH TREATMENT.

A MEDICAL man writes: "Will any reader kindly say what is meant by the Nauheim bath treatment and how it can be carried out at home?"

THE death occurred at Keymer, near Brighton, on Saturday, June 11th, of Mr. George Prentis Shepherd, at whose expense the convalescent home in Brighton-road, Worthing, was built and endowed in memory of his wife. The home is in connexion with the Royal Surrey County Hospital at Guildford, in which town Mr. Shepherd resided for very many years, carrying on the business of a chemist. Mr. Shepherd was born at Maidstone in 1827.

Lex will obtain the information he requires from the secretary of the Law Society, 100, Chancery-lane, London, W.C., or from the Council on Legal Education, 15, Old-square, Lincoln's Inn, W.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

WEDNESDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (Sixth Meeting). Re-opened by Dr. W. d'Este Emery, and continued by Dr. W. Camac Wilkinson, Dr. A. C. Inman, Dr. P. Watson Williams, Dr. David Lawson. Sir Almroth Wright will reply.

THURSDAY.

NEUROLOGICAL SECTION (Hon. Secretaries—E. Farquhar Buzzard, Wilfred Harris): at 8.30 P.M.

Pathological Meeting.

Papers:

Dr. Walter K. Hunter (Glasgow): Acute Degenerative Changes in the Nervous System, as Illustrated by Snake Venom Poisoning.

Dr. H. R. Dean: Results of the Examination of the Serum of Idiots by the Wassermann Reaction.

Dr. Farquhar Buzzard and Dr. Hinds Howell: Secondary Growths affecting Spinal Roots.

Dr. Wilfred Harris and Dr. B. H. Spilsbury: Acute Cerebral Softening due (?) to Venous Thrombosis.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.C.

TUESDAY.—8.15 P.M., Dr. H. W. Hake: On Ferro Silicon with Special Reference to the Poisonous Gases Liable to be Evolved Therefrom.—Dr. C. Mercier: The Lunacy Certificate and the Liberty of the Subject.

ROYAL STATISTICAL SOCIETY, Rooms of the Royal Society of Arts, John Street, Adelphi, W.C.

TUESDAY.—5 P.M., Dr. T. H. C. Stevenson: Suggested Lines of Advance in English Vital Statistics. 6.30 P.M., Annual General Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Dr. F. W. Andrewes: The Behaviour of the Leucocytes in Infection and Immunity.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Mr. M. Yearsley: The Duty of the General Practitioner towards Deaf Children.

TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M. Lecture:—Dr. L. Guthrie: Some Nervous Disorders in Childhood.

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. U. Pritchard: Menière's Vertigo.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Museum Demonstration. 5.15 P.M. Lecture—Dr. W. Hill: On the Great Value of the Œsophagoscope in Diagnosis and Treatment (with an Endoscopic Demonstration on Living Subjects).

FRIDAY.—4 P.M., Dr. D. McKenzie: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. R. Lloyd: Anæsthetics.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 11.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 3 P.M., Lecture (at Claybury Asylum):—Dr. R. Jones: Treatment of Varieties of Insanity.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: The Mouth in Health and Disease.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Intestinal Obstruction.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstrations of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Bernstein: Blood Examination (continued).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie). 4.30 P.M., Demonstration:—Mr. A. H. Pirie: The Treatment of Nævus by Radium and Other Methods.

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Dr. A. G. Auld: Pneumotherapy.

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Wells: The Pulse in Heart Disease.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Retrobulbar Neuritis.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

MONDAY.—5.15 P.M., Dr. F. Batten: Nervous Diseases in Children, illustrated by cases, specimens, skiagrams, and drawings. (Lecture IV.). (Post-graduate Course.)

TUESDAY.—5 P.M., Mr. O. L. Addison: General Surgical Diseases, illustrated by cases, specimens, skiagrams, and sketches. (Lecture III.). (Post-graduate Course).
WEDNESDAY.—5.15 P.M., Dr. H. Thursfield: Infant Feeding and Food Diseases, illustrated by cases, specimens, skiagrams, and drawings. (Lecture I.). (Post-Graduate Course.)
THURSDAY.—4 P.M., Lecture:—Dr. Garrod: Demonstration of Selected Medical Cases in the Wards.—5 P.M., Mr. O. L. Addison: General Surgical Diseases, illustrated by cases, specimens, skiagrams, and sketches. (Lecture IV.). (Post-graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.
WEDNESDAY.—4 P.M., Lecture:—Dr. Young: The Diagnosis and Treatment of Cardiac Irregularities.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.
TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Nose.
FRIDAY.—3.45 P.M., Lecture:—Dr. D. McKenzie: Labyrinth.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.
TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. E. F. Buzzard: Cases.
WEDNESDAY.—5 P.M., Demonstration:—Mr. P. Sargent: Surgery of the Nervous System—Peripheral Nerves.
FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. D. Armour: Surgery of the Nervous System.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C. (in the Lecture Room of the Institute).
WEDNESDAY.—6 P.M., Brevet Lieut.-Colonel Sir W. B. Leishman: Anti-Typhoid Inoculation. (Harben Lecture.)

MANCHESTER ROYAL INFIRMARY.
TUESDAY AND THURSDAY.—4.30-5.30 P.M., Honorary Staff: Post-Graduate Clinical Demonstration (Medical, Surgical, and Special Departments).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (22nd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (23rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (25th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Situations wanted: First 30 words, 2s. 6d.; per additional 8 words, 6d.
Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.
Special Terms for Position Pages.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

The Croonian Lectures

ON

THE BEHAVIOUR OF THE LEUCOCYTES IN INFECTION AND IMMUNITY.

Delivered before the Royal College of Physicians of London on June 14th, 16th, 21st, and 23rd, 1910,

BY F. W. ANDREWES, M.A., M.D. OXON., F.R.C.P. LOND.,

PATHOLOGIST TO, AND LECTURER ON PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.

Delivered on June 14th.

MR. PRESIDENT AND GENTLEMEN,—Before I commence these lectures I have two duties to fulfil, the one sad, the other pleasant. I must, in the first place, deplore the circumstance which has led to my standing before you to-day. The death of Dr. Arthur Gamgee, who was to have been your Croonian lecturer this year, has left a void which it is hard to fill. I cannot hope to carry out the task as he would have done. The loss which we suffer is not ours alone but that of the whole world of science and of medicine. I have next to offer my thanks to the College for the honour conferred by asking me to deliver the lectures in his place. In any case an unworthy substitute, I must crave your special indulgence in view of the fact that I have had only a year for the preparation of my subject, instead of the two which are by custom allowed to the Croonian lecturer.

In the year 1906 it was my privilege to deliver the Horace Dobell lecture before this College. I then endeavoured to picture the stages through which I conceived bacteria to have passed in the course of their evolution into pathogenic agents and the gradual development of those powers of aggressive parasitism which, at the present day, render them such dangerous foes to the animal body. I could have wished to use the larger opportunity afforded by Dr. Croone's foundation, by taking as my subject the converse theme—the evolution of the means of defence possessed by the body against invading microbes—and to trace it from its earliest beginnings to the complex mechanisms which we see brought into play in the human body. Such a task, however, I found beyond my powers, for our knowledge of the means of defence in the lower animals is very scanty, and time failed me for any serious attempt at its investigation. I have nevertheless ventured to choose for my subject one part of the field of immunity—as I think a very important part. It would be presumptuous for me to attempt to deal with immunity as a whole: I have not the learning or the critical power for such an enterprise. But in one part of the field I have worked, and in view of these lectures worked very specially—that, namely, which concerns the behaviour of the leucocytes in connexion with infection and immunity. During the last 20 years so much of the investigation of immunity has been devoted to the purely "humoral" side of the subject, that I feel it worth while to recall your attention to the cellular elements concerned in defence. While most of the facts which I shall have to put before you are the result of my own observations, I cannot avoid reference to current doctrines of immunity, and I must here own my indebtedness to the critical writings which have appeared during the last few years—those of Metchnikoff and Levaditi, of Ehrlich, Bordet, Pfeiffer, Sauerbeck, Wright, and many others. My own observations have been in the main experimental, derived from a study of the behaviour of the leucocytes in the rabbit under various conditions of infection and immunity, but I shall endeavour to harmonise them with known clinical facts in human disease.

I propose, in the first place, to put before you a short historical sketch of the development of our knowledge as to the part played by the leucocytes in repelling microbic aggression, after which I must perforce attempt to assess the rôle of the leucocyte in immunity. Having thus stated what I conceive to be the present state of our knowledge on the subject, I shall deal at greater length with my own observations on the leucocytes and the conclusions which I am disposed to draw from them.

The Croonian lecturer enjoys a wide range of choice in the selection of his subject, but I can imagine none which would more thoroughly fulfil the intentions of the founder, could he revisit the College after more than 200 years, than one which so directly concerns the prevention, control, and cure of disease.

HISTORICAL SKETCH.

We owe to Metchnikoff the first serious attempt to explain the resistance of the body against bacterial invasion. The crude and speculative views which had previously been put forward by Pasteur and Chauveau were based upon the supposition that the animal body was a mere culture medium for the growth of micro-organisms which might become exhausted of the necessary pabulum or choked up by bacterial products. Metchnikoff first formulated the conception of an active bodily defence, finding its mechanism in the functions of certain cells of the body.

THEORY OF PHAGOCYTOSIS.

It was already known that the amœboid movements of the leucocytes enabled them to take up foreign particles into their interior. Virchow was aware of the increase of circulating leucocytes in certain septic conditions. It had even been suggested by Panum in 1874, and by Roser in 1881, that bacteria might be ingested by leucocytes. But it remained for Metchnikoff to develop the idea that certain cells possessed as a normal function the power not only of ingesting but of digesting and destroying foreign particles and fragments of dead tissue. Amongst the foreign particles thus destroyed he found invading parasitic organisms, and he came to regard the process, which he named "*phagocytosis*," as the main, and indeed the only, defensive agency of the body against bacterial invasion. He first propounded this doctrine in 1883.

Metchnikoff was a biologist and his views were founded upon the long series of patient studies upon the lower forms of life recorded in his well-known work on inflammation. He was able to bring forward evidence of a uniform phagocytic process occurring from the lowliest up to the most specialised members of the animal kingdom, and this breadth of view helped to gain acceptance for his theory. Nor can it be doubted that the fact of his having commenced his studies in lowly invertebrates, where the means of defence are in their simplest and most primitive condition, played no small part in the reasoning by which he built up his hypothesis.

The fundamental starting points of the theory were—(1) the observed phenomena of intracellular digestion, and (2) the behaviour of the mesoblastic tissues in presence of foreign particles. Practically all phagocytic cells were found to be of mesoblastic origin, and Metchnikoff divided them into "macrophages"—fixed tissue cells which more particularly took up cell débris, and "microphages"—the leucocytes, and especially the polynuclears, whose more particular function it was to deal with micro-organisms.

At this early stage of the theory of phagocytosis the matter appeared simple enough. Successful phagocytic defence implied immunity, failure meant susceptibility. The phagocyte was the only means by which the body repelled microbic attack; the properties of the microbe were not yet discovered, and the influence of the fluids of the body had not entered into anyone's mind. From the first the simplicity of the theory and the readiness with which its central fact could be verified gained it wide acceptance.

It may have been an accident that the date at which Metchnikoff drew attention to the leucocytes as defensive agents coincided with a period at which increasing attention began to be paid to the morphological study of the blood. This was for the first time rendered accurate by the staining methods devised by Ehrlich's chemical ingenuity and summed up in his monograph of 1891. Instruments of precision had further been introduced, such as the hæmocytometer, by which the content of the peripheral blood in red and white cells could be exactly ascertained.

The impulse thus given to the clinical study of the blood bore rich fruit and a new branch of pathology arose—"hæmatology." During the last decade of the nineteenth century important monographs appeared in quick succession, amongst which I may mention those of Rieder, Türck, von Limbeck, Cabot, and Grawitz. So valuable has the study proved that it is now of daily application in clinical pathology. As regards infective disease its importance has proved twofold. It has become a well-established fact that

in some infections there is a marked increase in the number of circulating polynuclear leucocytes, in others none, in a few an actual decrease. A diagnostic value may thus attach to the leucocyte count. It is further established that in those infections habitually attended by an increase in the polynuclear count, the presence and extent of this increase serve as some sort of index of the power of the body to react against the infection. In other words, the leucocyte count has at times a prognostic import.

This has come about quite independently of Metchnikoff's theory as a direct result of clinical observation on human disease. But it indirectly supports his views, for it points to one special cell—the microphage of his terminology—as of high moment in the bodily reaction against certain infections. It would seem that the capacity of the body to produce and put into circulation an adequate number of polynuclear leucocytes in response to infection has in some cases a determining influence in recovery.

HUMORAL THEORIES OF IMMUNITY.

While the doctrine of phagocytosis was at first received with much favour subsequent developments in knowledge tended to throw it, for a time at least, into the shade. It was shown that the fluid elements of the blood, judged from the properties of the serum in experiments outside the body, were able to destroy bacteria apart from the direct coöperation of cells. This power, first noted by Fodor in 1887, was further studied by Nuttall, Buchner, Hankin, and others, and in 1889 Buchner propounded his well-known "*Alexin*" *theory*, in fundamental antagonism to the views of Metchnikoff. Buchner's original conception of alexin was that of a non-specific protective substance existing in normal blood serum, acting upon bacteria after the fashion of a ferment, and easily destroyed by heat, or, indeed, on mere standing outside the body. He suggested its possible origin from leucocytes. To this somewhat primitive conception may be traced the elaborate humoral theories of immunity which have since so largely held the field.

It would take me too far from the subject of these lectures to enter in detail into the history of all these humoral views I will only mention the more important landmarks. In 1892 Behring was able to announce the discovery of antitoxins in tetanus and diphtheria, and thus first arose the idea of *chemical immunity*. As a sequel to this came the discovery of *passive* immunity, produced by the transference of the specific antibody in the serum of an immune animal to a normal one.

Although Buchner and others had proved the destruction of bacteria by a suitable serum, Pfeiffer, in 1894, first placed the doctrine of *bacteriolysis* upon a firmer basis and indicated the dual nature of the active substance. In the following year Bordet elaborated and amplified this idea, formulating a doctrine of lytic action which has since gained universal acceptance, and which was later extended by Bordet himself to cover the phenomena of hæmolysis.

At this period Ehrlich was developing his theory of antitoxin formation, and he went on to study lytic action and other humoral phenomena. The bent of his mind was essentially chemical, and he succeeded in framing a purely chemical theory to account for the nature, properties, and formation of all humoral antibodies. This—the celebrated "*side-chain theory*"—was enunciated by Ehrlich in the closing years of the last century. It is impossible to withhold our admiration from a generalisation based on such a wide groundwork of facts, and serving to explain, in terms of exact chemical science, the processes of cell chemistry in general, and immunity as a special instance of these. So immediate was the recognition of the intellectual value of the side-chain theory, so lucidly did it seem to explain and reconcile the facts of immunity, and so fruitful did it prove in the stimulation of research, that it speedily became the dominating influence in our views as to the defence of the body against bacterial invasion. The disciples of Metchnikoff, at least in Germany, and indeed in this country, hid their diminished heads, and phagocytosis was relegated to the position of an interesting but relatively unimportant adjunct to humoral means of defence.

In France this was less the case, but Metchnikoff was compelled to meet the new facts: the primitively simple conception of phagocytosis had to be modified and amplified in such fashion as to include the action of humoral elements. The "alexin" of Buchner and Bordet, which is the "complement" of Ehrlich, was for Metchnikoff a product of the phagocytes, essentially intracellular in the living cell, but liberated on its disintegration. The doctrine of "*phagolysis*" was added to that of phagocytosis to explain the extracellular destruction of microbes. As we now know, there are many facts in support of the conception that alexin, or complement, is derived from the leucocytes. Later it became necessary to include the "substance sensibilisatrice" of Bordet, which is the "immune body" or "amboceptor" of Ehrlich in the scheme, and this Metchnikoff somewhat reluctantly did; he held it to circulate in normal blood, and as "fixator" to have an adjuvant action in phagocytosis. But these efforts at reconciling the facts of humoral pathology with the main doctrine of phagocytosis, though they were supported by numerous ingenious experiments, failed for the time to stem the current of humoral views, and for many years the views of Metchnikoff remained in comparative neglect.

OPSONIN THEORY.

Such was the position of affairs during the first year or two of the present century. The next landmark in the development of theories of immunity lies in the "opsonin theory," under which I include all those views which recognise phagocytosis as the essential means of defence, but consider the presence of a humoral element necessary to prepare bacteria for ingestion. The idea of such humoral coöperation was quite foreign to Metchnikoff's original theory, but in 1895 Denys and Leclef, working at immunity against streptococci, showed that the difference between the immune and the normal animal lay, not in the leucocytes but in the presence of a specific humoral element in the serum which determined the occurrence of phagocytosis. The experiments by which they proved this were ingenious and conclusive; it is a matter for some surprise that they did not arouse more widespread attention, for in this and in the later work of the Louvain school certain of the fundamental positions of the opsonin theory were clearly anticipated, including even the anchoring of the effective substance by the specific bacterium.

Nevertheless the credit of the opsonic theory belongs essentially to Wright. In 1903 Wright and Douglas proved the presence in *normal* serum of a humoral element which determines the occurrence of phagocytosis. They coined for it the name "opsonin," and showed that it was thermolabile, putting it forward as a substance hitherto overlooked. The acceptance of the opsonic theory in this country was in the main due to the immediate practical application to which Wright turned it. He devised a method of measuring the opsonic value of a given serum and employed the "*opsonic index*" as a guide in the application of the "vaccine" treatment which he was then beginning to develop. The brilliant results which this method of treatment has yielded in suitable cases drew immediate attention to the methods by which Wright had been guided in the dosage and administration of his vaccines. The opsonic index became almost a household word, and in this country and in America a very large amount of work has been carried out on the subject. On the continent the opsonic theory made slower headway, though it has now attained due recognition there also. It is a little singular that although the opsonic doctrine presupposes Metchnikoff's theory of phagocytosis as its basis, Wright himself, if we may judge by his writings, is practically a humoralist in the sense that his attention is concentrated on the humoral adjuncts to phagocytosis: to this point I shall return later.

Wright's opsonin, as found in normal serum, is a thermolabile substance. In the year following his original publication Neufeld and Rimpau drew attention to the presence in immune sera of a similar humoral substance, conditioning phagocytosis, but differing from Wright's opsonin in that it was thermostable. This they termed "*bacteriotropin.*" We now know that there are several substances adjuvant to phagocytosis differing in their thermostability. The term "opsonin" may conveniently be used as a generic one, and there is no reason for separating the bacteriotropin theory of Neufeld and Rimpau from the opsonic theory of Wright. The question which now occupies the minds of students of immunity is the relation between opsonins and previously known antibodies. Are they truly substances *sui generis*, or are they our old friends amboceptor and complement under

another name? Time will show, but there is a growing body of opinion that opsonic action is only a newly recognised manifestation of substances already known from other aspects. In any case the discovery has helped to bridge the gulf between phagocytosis and the purely humoral view of immunity, and to reinstate Metchnikoff's doctrine as to the essential nature of bodily defence against bacterial invasion.

AGGRESSIN THEORY.

More recently a somewhat new turn has been given to the point of view from which we may look on immunity by the "aggressin theory" of Bail. All the preceding theories have as their starting point the reactions of the body against invading bacteria. The aggressin theory more logically begins with the properties of the parasitic organism. It denies that the various lytic antibodies, interesting as they may be in test-tube experiments, have much to do with immunity in the animal body; in the tissues, where infection runs its natural course, bacteriolysis does not occur. Bail focusses his attention in the first place upon the means by which the bacterium is enabled to multiply in the body. Assuming phagocytosis as the essential means of bodily defence, it is plain that any property which enables the bacteria to paralyse the phagocytes must facilitate their invasion. This property is found by Bail in substances formed by pathogenic bacteria, chiefly within the animal body, which he terms "aggressins," and which are supposed to act by negative chemiotaxis upon the leucocytes; otherwise he imagines them to be non-toxic. Immunity, on the aggressin theory, depends upon the formation by the body of "anti-aggressins," which once more permit the phagocytes to exercise their normal functions of defence. An anti-aggressin is obviously but an opsonin under another name. Only the point of view has been changed. Logically the change is, perhaps, for the better, for the bacterium is always the attacking element, and the names which we choose to apply to the weapons in the hands of the attacking and defending forces are a matter of detail.

It cannot be said that Bail's theory has gained wide acceptance, and it may well be that his facts as to the specific nature of aggressins are capable of interpretation in another way. Nevertheless, the aggressin theory has drawn attention to means by which bacteria may defend themselves against the mechanisms brought against them by the body. Amongst these must be reckoned the remarkable structural change which, in the case of some species of bacteria, has been shown to occur in those individuals which have successfully invaded the animal body—in other words, which are in a highly virulent condition. The change consists in the development of a capsule, often of great thickness. So long ago as 1897 Bordet showed that streptococci might under these circumstance develop a capsule which apparently hindered their ingestion by phagocytes. There seems to be a relation between the virulence of the pneumococcus and the degree of development of its capsule. The anthrax bacillus affords another striking example of the same thing, well shown by the work of Gruber and his pupils. It would seem that when bacteria are experimentally introduced into the animal body (and there is no reason for doubting that the same process occurs in natural infection) the majority perish. These are the more weakly ones, least able to withstand the defensive mechanisms of the body. If the invasion is successful, the victorious host consists of the lineal descendants of the more capable survivors, inheriting their parents' capacities. The rapidity with which generation succeeds generation (which may be a matter of only half an hour) enables natural selection to act with unparalleled intensity, and thus a resistant—i.e., a virulent—strain of the microbe is speedily produced. The properties essential to virulence are seen to become kinetic in the very course of the infection; in the test-tube they were merely potential. Thus is simply explained the exaltation of pathogenetic power long known to result from passage through the body of a susceptible animal. In some cases at least the phenomenon is associated with the development of a well-marked capsule; in others, merely with an increase in the apparent size of the bacterium. The term "animal bacilli" has been employed for such strains, as opposed to the "culture bacilli" of the test-tube. The evidence that such strains owe their virulence to the power of resisting the natural defensive mechanisms of the body seems clear as regards phagocytosis. I have already mentioned Bordet's observations on streptococci. Gruber and his co-workers have shown that capsuled anthrax bacilli resist phagocytosis, where the uncapsuled ones succumb. Rosenow has demonstrated the inverse relation between the liability of pneumococci to phagocytosis and their virulence. It has even been shown that, in a given case of pneumonia, the pneumococci cultivated from the lung were susceptible to phagocytosis, while those cultivated from the blood resisted it.

All this so far supports Bail's conception in that it begins the study of immunity from the point of view of the bacterium. Whether or not the microbe forms chemical aggressins it at least exhibits structural adaptations which enable it to defy the defence of the body. It may be that the converse proposition is justified and that the body defends itself against the bacterial poison by some analogous structural adaptation; hypotheses of immunity on such lines have been suggested by Sauerbeck, Wassermann and Citron, and others.

Such are the chief views as to the immunity of the body against bacterial invasion which have been held during the past quarter of a century. There are indeed others, but they are too novel or too little supported by facts to be included in this short historical survey. I may add that, during the last few years, an altogether new fact has also been brought to light, evidently closely connected with immunity, and so far only explained by chemical hypotheses. I refer to the phenomenon of supersensitisation to alien proteins, known as "*anaphylaxis*." No intelligible theory of immunity has yet been founded upon the phenomenon, and I mention it here only because I shall have later to describe my own observations on it in relation to the behaviour of the leucocytes. I shall enter fully into the subject in another lecture.

SUMMARY AND CRITICISM.

I must now ask your permission to look back over the history which I have just sketched, and consider how much solid nucleus of established fact may, at the present day, be held to have condensed from the nebula of conflicting opinion about immunity.

We have seen that the first theory of active bodily defence was that of phagocytosis pure and simple, unconditioned by any humoral adjunct. The discovery of the power possessed by the higher animals of forming antibodies reacting, not only against bacteria, but against foreign cells of all descriptions, and even against foreign proteins and bacterial toxins, threw the simpler explanation of Metchnikoff into the shade, and humoral theories of defence reigned almost supreme for 10 or 15 years.

It is fatally easy to explain a newly observed property by assuming a hitherto overlooked substance in the serum. I do not for a moment desire to cast any doubt on the truth of the fundamental propositions of lytic action: they are most firmly established. But it is plain that a school of thought which translates the observed properties of a fluid into terms of personified entities for which there is no actual chemical evidence is not without its scientific dangers. Not till antibodies and their antigens have been brought under the dominion of weights, measures, and chemical formulæ, not until their chemical and physical properties have been ascertained by methods lying outside biology, shall we be able to feel sure that we are dealing with things and not phantoms. In other words, the solid and final advance in our knowledge of humoral immunity must come from the development of physical chemistry. To explain biological facts by a transcendental pseudo-chemistry may be useful enough as a working hypothesis so long as we are content to recognise it as such.

Metchnikoff's view was essentially based upon the facts of natural immunity, while humoral theories have been chiefly derived from the study of the acquired property. Metchnikoff, again, relies mainly upon what is observed to take place within the living body; the facts of the humoral school are chiefly based upon the behaviour of the serum in experiments carried on outside the body. There is much to be said against the assumption that the serum of shed blood necessarily corresponds in its properties with the fluids of the living body. The gulf is not one to be lightly bridged. Could it be shown that the observed facts of immunity corresponded in all cases with the properties of the serum outside the body no serious difficulties would arise. But this is not the case. The instance of anthrax is

one often quoted: rabbit's serum is bacteriolytic for the bacillus, yet the animal is susceptible; the hen is immune, yet its serum has no bacteriolytic power against the bacillus. The doctrine of humoral antibodies, as Sauerbeck has urged, is not quite the same thing as the doctrine of immunity; the phenomena of the test-tube will not explain all that we see in the living body.

The established fact which emerges from all the humoral observations of the last decade and a half is that there exists a restricted group of foreign chemical substances to the presence of which the animal body responds in a special manner. This group—the so-called "antigen" group—is by no means synonymous with the group of poisons: the simpler chemical poisons are not antigens, and many substances, in themselves harmless, may nevertheless act as such. The group includes proteins of all kinds foreign to the affected organism, including bacterial proteins; it further includes bodies of unknown but certainly complex composition, such as enzymes and bacterial toxins, together with certain other animal and vegetable toxic agents. The response of the body when such substances are introduced into it in suitably small doses is delayed for a period of some days or weeks. After this needful incubation period the serum is found to possess a new property—that of reacting with the antigen in such fashion as to neutralise it. The action may be simple and direct, as in the case of toxin and antitoxin, or it may be more complex, involving two distinct properties, one of which is abolished by heating for half an hour to 55° C., while the other resists higher temperatures.

These are demonstrable biological facts which admit of no doubt or cavil. They are naturally, and probably rightly, interpreted as indicating the formation of chemical substances having the specific power of neutralising the antigen, chemically or physically. How and where they are formed, and how they interact with the antigen, is still a matter of speculation. By far the most ingenious explanation is that offered by Ehrlich's side-chain theory. There is, indeed, no other theory worth mentioning. We may well believe that the processes of cell chemistry are of excessive complexity, but it must be confessed that when, to the side-chain theory, there are added all the accessory hypotheses and corollaries which seem requisite to explain all the observed facts, we are rather staggered in our allegiance.

And when we further consider the relation of all this to the actual facts of immunity, we must feel somewhat sceptical as to the adequacy of these purely humoral explanations. Except in a few isolated cases there is little evidence as to the extracellular destruction of bacteria within the body by humoral agencies. There are certain bacteria which seem susceptible to such agencies; such are the cholera vibrio and perhaps the typhoid bacillus, but these are exceptions to the rule.

Modern opinion hence has during the last few years tended to swing back towards Metchnikoff's doctrine; not, indeed, in its original simplicity, but in the sense that the ordinary means by which invading bacteria are destroyed is phagocytic in essence, conditioned by the presence of a humoral element. The opsonin theory and the aggressin theory accept phagocytosis as their basis, and we may regard an opsonin and an anti-aggressin as much the same things under different names. Numerous and somewhat conflicting attempts have been made to identify opsonins with lytic antibodies. The thermolabile opsonin of normal serum is identified with complement by Muir and Martin, Gruber, and others. The thermostable opsonin of immune serum may be identical with an ordinary lytic amboceptor, as Dean has argued. Sauerbeck suggests that opsonic action and lytic action may be different degrees of the same process. To enter into the arguments would lead me too far from my subject. It is certain that the means of defence against bacterial invasion is not in all cases identical. The body employs different means according to the nature and properties of the attacking organism.

IMMUNITY AND EVOLUTION.

If I may venture to express the view of immunity which appeals to me I shall do so from the standpoint of evolution. An infective disease represents a struggle between the invading microbe and the body of its host. Each party in the conflict possesses its own weapons of offence or defence, specially adapted to counteract those of the other party. In my former lecture before this College I endeavoured to indicate the probable course of evolution in a conflict of this sort. I compared the gradually increasing complexity of the situation to a game of chess, in which the bacteria had always been the attacking side. It is reasonable to assume that at the earliest dawn of infective disease upon this earth the invaders, probably accidental ones, were unprovided with any special weapons of offence, and were no more to the host than any other inert food particles. To repel such casual intruders the body required no special means of defence. The process of phagocytic ingestion followed by intracellular digestion probably sufficed. Intracellular digestion is the primordial form of that function; seen to perfection in the amœba, it is still carried out by the mesoblastic cells of animals higher in the scale. Such, I take it, must have been the germ from which the battle of infective disease originally sprang. The primitive means of bodily defence must almost inevitably have been phagocytic. It must have included the two factors of *ingestion* and of *digestion* by whatever enzyme the cell possessed for its normal nutritional processes. It is possible that in certain cases of infection, as we see it to-day in the higher animals, these factors have become in a measure dissociated. The serum may possess the power of extracellular disintegration of certain bacteria, but it may quite well be that this is due to an active agent which is primarily intracellular. On the other hand, bacteria may be ingested by phagocytic cells without any sign of intracellular digestion; in gonorrhœa the cocci seem to thrive in the phagocytes.

In any case it seems to me impossible to doubt the truth of Metchnikoff's doctrine as the starting point of bodily defence against bacteria in bygone ages. His studies in comparative pathology show that phagocytosis remains the most essential method of repelling microbic invasion, up to the higher vertebrates. In man himself we see a process fundamentally identical, and still essentially a property of the mesoblast, but long before we reach this point we find various complicating factors introduced into the struggle. These fall naturally into two groups: (1) the development of aggressive weapons by the attacking force; and (2) improvements in the means of defence on the part of the body attacked. It is logical to consider them in this order.

EVOLUTION OF THE PATHOGENIC BACTERIA.

In my Horace Dobell lecture I endeavoured to trace the evolution of the pathogenic bacteria. Starting from the obligate saprophyte, I suggested the next stage as one of permanent attachment to the surfaces of the animal body, external and internal, still as a saprophyte, but with occasional chances of access to the blood and tissues. Following this must have come a stage at which the bacterium developed the power of taking advantage of these chances and of living for awhile as a facultative parasite. The parasitic power, once acquired, seems in certain species to have become highly developed, so highly in some cases that other modes of life were no longer necessary. Thus must have arisen the obligate parasites, spreading as pathogenic agents from case to case.

What, now, are the means by which the microbe has succeeded in acquiring the power of growth within the living tissues? From the very outset it must have been confronted with the phagocytic powers of certain cells of the body. It is reasonable to assume that the first thing a bacterium had to do in order to invade the living body with any prospect of success was in some way to antagonise the action of the phagocytes. If one wishes to gain access to a pleasant garden guarded by fierce dogs there is more than one way of attaining the end in view. One might put on armour, or by chemical means one might render oneself so physically unpleasant to the animals that they would shrink away in disgust; or again one might poison the dogs. All these things, in varying degree, bacteria seem to have done; we can trace to-day, amongst virulent bacteria, indications of all three methods of antagonising the defensive mechanisms of the body, but we cannot say which method arose first. I have mentioned the formation of capsules by certain bacterial species—structures which, according to many reliable observers, in some way hinder phagocytosis. There is again evidence that certain bacteria or their products exercise a repellent influence upon the leucocytes, a negative chemiotaxis. This conception lies at the root of

Bail's aggressin theory. Again, we know that many pathogenic bacteria produce toxins acting on various cells of the body, sometimes with great severity. Although Bail regarded his aggressins as non-toxic some of his critics do not share this opinion (e.g., Sauerbeck), and it is possible that negative chemiotaxis may represent a minor manifestation of toxicity.

Such seem to be the weapons of offence and defence in the hands of the bacterial army. By their aid the microbe succeeds in eluding the defensive agencies of the body, for it must be remembered that infective disease is a reciprocal affair, and that there is an immunity of the bacteria against the body no less than an immunity of the body against the bacteria.

Improvements in Bodily Defence.

Let me now turn to the opposite side of the conflict and consider the improvements in bodily defence which have been evolved in the higher animals in response to bacterial assaults. I start with the supposition that phagocytosis is a fundamental power of certain cells of the body, adequate for defence against microbes which have no special powers of aggression. It probably still suffices for such bacteria. I have conducted a few experiments in which I have injected into the circulation of animals harmless air and water bacteria, which, being incapable of multiplication at the temperature of the body, may certainly be regarded as devoid of any active powers of aggression. I will give the details of these experiments in due course. Here I will only say that the immunity reactions which I have observed in such cases are of trivial extent compared with those excited by more highly specialised pathogenic bacteria. These harmless organisms are so readily destroyed within the body, even when injected in immense numbers, that it would seem hardly worth the body's while to have developed any special means of defence against them.

But as soon as we turn from these necessarily impotent species to bacteria which have acclimatised themselves, as saprophytes, to the physical and chemical conditions obtaining in the animal body, and which have had chances in the past of occasional access to the tissues, we find coming into play factors other than spontaneous phagocytosis. These factors become more and more conspicuous and important in defence as we pass on to those microbes which have developed the power of aggressive parasitism. It may be noted, however, that even in the latter case some traces of spontaneous phagocytosis still survive. In any bacterial culture which is used for an opsonic experiment there are a few weakly and degenerate individuals which are ingested, even in the absence of opsonin. If, for example, we look at the protocols of the experiments in the original paper of Wright and Douglas the controls with washed leucocytes are not absolute blanks, though the ingested bacteria are exceedingly few in comparison with those taken up in the presence of serum; I take them to represent decadent bacteria devoid of any powers of resistance. I may further refer to the experiments of Rosenow, who found that pneumococci lost their power of resisting phagocytosis on prolonged culture. In one strain, long cultivated and wholly non-virulent, he found that phagocytosis took place freely in absence of opsonin. Spontaneous phagocytosis—i.e., phagocytosis occurring in absence of any humoral adjunct—seems still to occur, according to the testimony of many observers, where a pathogenic organism has reverted to complete impotence; in any culture there are likely to be some individuals in this condition.

But although this is so, it is certain that, in the struggle against those pathogenic organisms whose invasion of the body causes its commoner and more serious infective diseases, spontaneous phagocytosis plays little or no part. It is amply proved by the work of those who have founded and developed the opsonic doctrine of immunity that in experiments outside the body a humoral element is needful to act upon the bacteria before phagocytosis can take place. It is impossible to prove this point in the same way under the conditions occurring in the body itself, but there is every reason for the belief that experiments *in vitro* here, at least, afford safe ground for arguing as to what obtains *in vivo*. The property which is personified under the term opsonin would appear to have become an integral part of the means of defence against pathogenic bacteria.

I conceive this factor to be the chief improvement which evolution has effected in the primitive means of phagocytic defence. At first a function of the mesoblast, as a whole, it would seem that phagocytosis, so far as the destruction of bacteria is concerned, has chiefly been relegated to the polynuclear leucocytes. This is the explicit opinion of Metchnikoff, and it accords well with observed facts both within and without the body. I know of no evidence that the actual processes of ingestion and digestion have undergone any striking change in the course of evolution. The modern polynuclear leucocyte may be more active and efficient than its remote mesoblastic ancestor, but I think that is the most that can be said.

There is, however, a further respect in which it is reasonable to assume that improvement has been effected. We are entitled to believe that the polynuclear phagocytes have developed increased powers of scenting their prey from afar. The evolution of a closed blood vascular system has vastly increased the readiness with which the wandering cells can be concentrated on any given spot. The mechanism by which this is accomplished seems to be a physico-chemical one. In presence of a local tissue attack by certain micro-organisms, and notably by the pyogenic cocci, we find that the polynuclear leucocytes tend to converge upon this spot from all over the body, and this with truly remarkable rapidity. So prompt is the reaction, so obviously purposeful its aim, that it is at first sight difficult to believe it anything but an intelligent response on the part of the active agents. When the police assemble to suppress a street disturbance, we naturally attribute the fact to intelligent action on their part, though even here we are apt to overlook the discipline and routine which really render the phenomenon almost mechanical. We cannot, however, seriously attribute conscious and intelligent action to the leucocytes. I do not quite know why, because I do not know what consciousness and intelligence really are, but the tendency of modern science is to seek for the most prosaic explanation of all observed facts.

In this case a sort of physico-chemical explanation is forthcoming. It is believed, on good experimental grounds, that cells or syncytia capable of amœboid movement are governed, as to the direction in which they move, by chemical stimuli. This is the doctrine of *chemiotaxis*, established by Pfeffer, Stahl, and others. One chemical substance may attract the mobile cell, another may repel it. Chemiotaxis may be positive or negative. Precisely how the chemical substance acts is a matter of speculation, but there are experimental grounds for supposing its action due to changes in surface-tension. Certain bacteria are observed to exert a positive chemiotactic action upon the polynuclear leucocytes; in the case of other bacteria this action is lacking or is replaced by a negative chemiotaxis. It is assumed that those infections which are specially associated with a dense congregation of polynuclear leucocytes—e.g., suppurative processes—owe this peculiarity to a specially intense positively chemiotactic influence on the part of the infecting organism or its products. In presence of a local pyogenic infection the leucocytes are attracted from the blood passing through the neighbouring vessels and are to be seen in active emigration into the affected focus. More than this, the assumed chemical influence, wafted by the blood-stream, appears to attract out into the current the reserves of leucocytes present in the bone marrow, explaining the circulatory leucocytosis observed under such conditions.

All this is commonly admitted and taught; my only reason for referring to the matter lies in its relation to the process of evolution. It is inconceivable that the bacteria should have gone out of their way to develop chemical substances attractive to their hereditary foes. The man who hates cats does not spread valerian root in his back garden. But it is readily conceivable that the more mobile phagocytes should have become educated to respond to the chemical aroma of the natural foes of the body. On such lines it is intelligible that the phagocytic reaction against intruding microbes may have become specialised and improved, and such considerations may perhaps explain why this reaction has been relegated to the mesoblastic cells specially able to respond to chemiotactic influence.

Development of Humoral Adjuncts to Phagocytosis.

These speculations concern only spontaneous phagocytosis. I must next consider how that important adjunct to the process—opsonic action—can have arisen. Here I can be very brief, for the opsonic school has not yet furnished an

evolutionist to trace back the process to its earliest beginnings, as Metchnikoff has done for the more central factor of phagocytosis itself. Such a research would be full of interest, and had the time at my disposal been longer I should have attempted it. But as matters stand we are wholly ignorant of how far down the animal scale opsonic action can be traced, and it would be futile to speculate on its origin. There are, nevertheless, certain fundamental facts which cannot be overlooked.

If we believe spontaneous phagocytosis to have been the primitive means of defence, and if it be conceded that in the evolution of the processes of infective disease the bacteria have always been the attacking side, it is difficult to avoid the conclusion that the more highly developed pathogenic bacteria, against which alone opsonic action has hitherto been adequately studied, have acquired the power of neutralising spontaneous phagocytosis, presumably by developing some chemical substance repelling the phagocytes. At first sight this may appear to contradict what I said just now in considering the education of the leucocytes to respond by a positive chemiotaxis to the presence of bacteria. But we are considering two different things—spontaneous phagocytosis and opsonic action. I do not find it illogical to conceive that certain inherent products of the natural bacterial body may have become positively chemiotactic to the leucocytes—thus explaining the facts of spontaneous phagocytosis—while believing that the more highly specialised parasites have secondarily acquired the power of producing another chemical substance which may keep phagocytosis in abeyance. It would be this substance which confers "virulence," and it would be an "aggressin" in Bail's sense. The inverse relation between virulence and opsonic action compels us to admit something of this kind, and I submit that the first move in this game must have come from the bacteria. So far, I consider the aggressin theory justified, and it may be conjectured that an opsonin is a substance which antagonises the aggressin and permits the normal positive chemiotactic influence of the bacterial body upon the leucocyte to resume its sway.

We have next to ask how and in what connexion did these humoral adjuncts to phagocytosis come to exist. If we believe an opsonin to be a substance apart, having nothing to do with the lytic antibodies, we cannot guess its primitive origin till we have the data as to its presence or absence in the various lower animals. But if it be conceded that opsonic action is probably only a newly recognised manifestation of antibodies already known (and there is increasing reason for this belief) we may with some probability trace it back to the phenomena of primordial cell nutrition. This conception of humoral antibodies has been developed by Metchnikoff to some extent, but in far greater detail by Ehrlich, in whose hands it became the very basis of the side-chain theory. The substances capable of acting as antigens are foreign proteins or allied substances, of a kind which must have served as food from the beginnings of animal life. It is conceivable that the simple processes of intracellular digestion by enzymes may have become elaborated in the course of time and in the higher animals into a response to the presence of all food-like substances, even when these are harmful, by which the primitively digestive secretions act as neutralising or destructive antibodies. These may be liberated from the attacked cell by disintegration, as Metchnikoff's idea of phagolysis suggests, or may be cast off from it by over-production, due to over-stimulation, as Ehrlich would have it. In any case, the result would be a humoral antibody with the property of disintegrating and destroying, or at least injuring or neutralising, the antigen in question.

Ehrlich and Metchnikoff are at one in this, at least, that they trace back their conceptions of immunity to the phenomena of primitive cell nutrition. Ehrlich lays stress on the chemical and digestive aspects of the process, Metchnikoff on the mechanical fact of ingestion. We may candidly recognise the value of both factors in bodily defence against bacterial invasion and well believe that the body has, in the course of evolution, exploited every means in its power to antagonise the dangers which threaten it. In certain cases the effective means may have been purely chemical, and an antitoxic immunity in Ehrlich's sense may be the essential defence. In other cases the defence may be a purely phagocytic one, but this is nowadays rarely an unconditional and spontaneous phagocytosis, because the attacking agents are as a rule provided with aggressive powers. These require to be antagonised before phagocytosis can be accomplished, and to this end the body employs one or another of its lytic antibodies in what we term opsonic action. In exceptional cases the lytic antibodies can defend the body apart from direct cellular coöperation, but such immediate bacteriolytic action is seldom seen in the living tissues, though it can be produced in certain cases *in vitro*.

On some such lines as these I can dimly foresee a simplification, though not a unification of the present conflicting doctrines of immunity. I can believe them all traceable in their origin to the ingestion and digestion of a casual bacterium by an amœba. But I can believe this elementary process to have been elaborated in various ways into several different mechanisms of defence, some suited to antagonise one, some another kind of microbic assault. And it would appear that the body now employs whichever weapon is best suited to the immediate end in view, or which it happens to have at its command. Looking at the facts at present established, it appears that the essentially antitoxic means of defence is limited to a very small number of pathogenic organisms, and that the essentially bacteriolytic means of defence is equally limited in its application. In the great majority of cases the defence is in its essence phagocytic, but dependent upon opsonic action, an opsonin being a substance which neutralises the agency by which the bacterium attempts to ward off phagocytic attack.

ADEQUACY OF DEFENSIVE AGENCIES IN NORMAL CONDITIONS.

Whether or not this imperfect sketch of the means by which the warfare of the body with the bacteria which invade it is carried on, and of the stages by which it has been evolved in the past, is a true one, it is clear that the defensive agencies of the body are on the whole very adequate under normal conditions. We see the cutaneous and mucous surfaces of the body swarming with bacteria, many of which are potential parasites, yet health is, as a rule, undisturbed. And this is not because the bacteria do not gain access to the tissues. They do so to a degree which we are only beginning to realise. It is commonly taught that the normal organs and tissues are sterile, although the lungs and lymphatic glands are admitted to contain bacteria. Conradi has, however, recently shown that this is by no means the case; bacteria are not uncommonly present, though in such small numbers that special methods are required for their detection. He examined 162 portions of tissue taken fresh from the slaughter-house in oxen and pigs. The portions of tissue were rigidly sterilised externally by means of oil at 200° C., and then in 2 per cent. mercuric chloride. After this they were incubated at 37° C. for 20 hours in a sealed moist chamber, when cultures were taken from the interior of the mass. Of the 162 pieces of tissue examined no less than 72 yielded bacteria. In the case of the lungs 80 per cent. yielded growth; in the liver, 66 per cent.; while the kidneys and muscles showed growth in 31 and 30 per cent of the portions examined. The bacteria found were in order of frequency: B. coli communis, B. lactis aerogenes, Streptococcus acidi lactici, B. mesentericus, B. fluorescens non-liquefaciens, Diplococcus pneumoniæ, &c., pointing plainly to the intestine as their main source. We must give up the idea that the saprophytes of our mucous surfaces only occasionally gain access to the tissues; they evidently do so frequently, but they are present in the tissues in extremely sparse numbers, because the defence of the body is so good that they are done to death in a very short time.

More than this, bacteria, if not of marked virulence, can be artificially injected into the peritoneum or into the blood stream in immense numbers, with no disturbance of health and no inflammatory reaction. As regards the peritoneum, we know from the observations of Grawitz that even pyogenic organisms, unless of a virulent strain, can be injected without setting up peritonitis, provided that the volume of fluid in which they are suspended does not exceed the absorbent powers of that cavity. I shall have later to describe certain experiments in which I injected living bacteria into the circulation in rabbits, in doses of several hundred millions, and watched their disappearance from the blood stream by taking measured samples of the blood for culture every two minutes. Even the pneumococcus in full virulence fell very rapidly in numbers till in a quarter of an hour they had fallen to about one-tenth of the number

first observed: harmless organisms disappeared even more rapidly. The disappearance of bacteria from the blood stream does not of course necessarily mean their destruction, but in the case of harmless bacteria the animals remain in perfect health, and there can be no doubt that disappearance from the blood is followed by destruction.

LINES OF DEFENCE AGAINST BACTERIAL INVASION.

It seems therefore clear that the defensive mechanisms of the body in health are not only fully adequate to deal with the bacteria which gain access to the tissues from the intestine and elsewhere, but that much larger numbers of harmless bacteria can be disposed of with equal readiness. Only when the resistance of the body is lowered by what we term the "predisposing causes" of disease, or when the strain of microbe gaining access is one of special virulence, is this normal equilibrium upset. Under ordinary conditions the work of defence ceaselessly goes on without any obvious fuss or disturbance. I have elsewhere spoken of this as the *first line of defence* against bacterial invasion.

But when this first line breaks down, and bacteria begin actually to multiply and hold their own in the tissues, leading to infective disease, a new phenomenon appears. A *second line of defence* is brought into play in which the resources of the body are concentrated upon the area attacked, should this be localised, as is usually at first the case. The work of defence is now by no means inconspicuous and tranquil; the chief clinical symptoms of the disease depend upon it, for it is the process which we term *inflammation*. The presence of a closed vascular system enables the body to concentrate upon any desired point both the leucocytes and the humoral elements which may be contained in the blood. I need not here insist that the phenomena of acute inflammation are essentially vascular, and that the outpouring of fluid and the emigration of leucocytes are its central features. It is true that acute inflammation is not necessarily of bacterial origin; it is a response to injury. But the commonest bodily injuries are microbic in origin, and there are few bacterial invasions which are not associated with inflammation. We now justly look upon inflammation as a defensive and reparative process—a means of defence brought into play, and usually with success, where a bacterial invasion threatens the body. Its actual weapons are not, perhaps, different from those employed in the daily extermination of casual invaders, but its clinical features depend upon the acute local vascular phenomena which enable these weapons to be concentrated upon the threatened area. Where the invasion is from the first general and the microbes multiply in the blood stream itself, we have a septicæmia in which the phenomena of inflammation are absent or scattered over various areas. This is commonly a fatal condition, but there are few septicæmias which are not secondary to a primitively local infection. Should the second line of defence be absent or fail, the condition of the patient is a grave one indeed.

There is another factor in the second line of defence which I will only mention here, because it lies outside my immediate subject—namely, the rise in bodily temperature which habitually attends acute infections. It is still *sub judice* how far fever is to be regarded as a defensive mechanism of the body, but there is much to be said in favour of such a view. It is clear that true fever, as distinguished from mere hyperthermia, is in the main associated with bacterial invasion, and there is evidence that a raised bodily temperature is inimical to pathogenic bacteria, attenuating their harmful properties.

I fear that in this lecture I have gone somewhat beyond the limits of my central theme. But it is plain that one cannot attempt to criticise the part played by leucocytes in immunity without reference to doctrines of immunity in general. I have tried to look at these from an independent and unbiassed point of view, though I am only too conscious of the imperfections of my sketch. In the following lectures I shall concentrate my attention upon the leucocyte and its behaviour in infection and immunity.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Richard Arthur Jones, L.M.S.S.A. Lond., of Menai Bridge, Anglesey, was recently presented by a ladies' class of first-aid, which he had instructed, with a set of military hair-brushes in a case on which are his initials mounted in silver.

ABSTRACT OF

An Address

ON

ANOMALIES OF THE MIND AND THE EVOLUTION OF THE MENTAL PROCESSES.

Delivered at the West London Post-Graduate College on June 8th, 1910,

BY ROBERT JONES, M.D. LOND., F.R.C.P. LOND.,

LECTURER ON MENTAL DISEASES, ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL; RESIDENT PHYSICIAN AND SUPERINTENDENT, LONDON COUNTY ASYLUM, CLAYBURY.

GENTLEMEN,—In order to study the anomalies of man's mind it is necessary to view mental processes from their evolutionary history not only ontogenetically but also phylogenetically, because the organic structure of the race is recapitulated in the individual. Originally endowed with only an automatic reflex, man has possibly risen from a simple protoplasmic reaction to the possession of purposive adaptation by muscular contraction, especially fitted for the necessities of his life, until we now see in his highly evolved state the possession of intellectual and æsthetic powers fully controlled by a directing will. Owing to the presence of this hierarchy of mental functions it is too often lost sight of that man is an animal subject to biological laws and liable to modification of type by variation as are other animals and all plants. That this is so is demonstrated by his mental state in dementia, in which the extreme shedding of the veneer of civilisation has occurred and he is presented to view with all the brutal reactions and the animal instinctive tendencies of his ancestral origin.

Man and animals have found the performance of certain actions appropriate and useful for the propagation and prolongation of their species, and when intelligent adaptations for this purpose are made by the individuals of one generation, these, so to speak, "set the direction" of the nervous organisation for the future performance of these actions which then tend to be performed by "organic selection" independently of learning. What we see in the lower animals we also see in man—the presence of an instinct of self-preservation, of sex and reproduction, of appetites and desires, hunting for food, seeking warmth and shelter, and herding for the common safety. In the various mental deviations from the normal we may witness the reversal of these instincts, and we may meet with some which are the result of variations or mutations, or which indicate a change in the mental content through the influence of time and environment.

The influence of the "environment" is an important factor in the estimation of mental unsoundness, although it is often overlooked. The organism (or the individual) and the environment constantly act and react on each other, and any defect of accommodation on the part of man is more often an indication of insanity than is the presence of any perverted instinct. Every person is sane or insane in relation to his own standard and in relation to his own environment, so that the environment must always be considered in estimating and realising the presence of insanity. To such a degree is this view accepted that sanity has been defined as the capability—more or less complete—which the individual has, of reacting normally to changing conditions in his environment. As the surroundings become more complex with the progress of civilisation, so there must grow an increased power of adaptation of the individual, and herein lies the denotation and connotation of insanity. The study of insanity takes notice of these relations, and the manifestations of the mind in response to both outward and inward stimuli become a prime factor. In dealing with the subject it is necessary to consider man in regard to his past as well as in regard to his future and his immediate present: in the words of Lavater, his relations to his environment are "retrograde, stationary, or progressive."

THE MECHANISM OF MIND.

Let us briefly consider the mechanism of mind. We know that we depend upon experience for our knowledge, and that experience comes to us through the avenues of the senses by objects presented to them. Such objects when presented are perceived—we see objects, hear sounds, feel matter, taste food, and smell odours. When the objects are presented to the senses they are fixed in consciousness by the memory, and these memory pictures are preserved, and when the objects are removed the pictures can be recalled and revived, so that the mind can react to objects as perception, or to the memory of objects, as ideas. Often also, the mind can react to ideas as abstract thoughts, upon which we can deliberate, and act after reflection.

It is quite clear that in the first instance our knowledge, our opinions, and beliefs must be based upon the supply of material to the mind direct from the senses—not only from the five special senses but also from muscular contractions, from the tendons, ligaments, and joints which give us sensations of pressure and equilibrium and of the proper balancing of the body. Nor are these all the avenues of information; there are those also connected with the inner vital organs, those from the sensations of heat and cold—which are distinct from touch, and which yield what is called the *cœnæsthesis* or the organic sensations. The various sensations thus experienced from the vital organs, as also from the joints and muscles and from the special sense organs, all tend to be associated together in some definite relation (i.e., assimilated), and such sensations are always flowing into the mind, where they give rise to an "awareness," being thus known or cognised. They are also further associated with a feeling of pain or pleasure. This feeling of pain or pleasure enters largely into the attitude the mind takes in regard to action and, as a rule, feelings of pleasure are associated with states of the body that are favourable to growth, whereas pain tends to depress the vital activity. When feeling is not directly connected with a presented object it is called an emotion, and the emotions of fear, hate, love, hope, disgust, &c., are fundamentally connected with conduct, and thus serve as powerful motives to action. These motives may conflict, and we are left with a sense that we can act as we "will"—i.e., we can weigh the motives, deliberate over them, and resolve to act after reflection. It is this will power—viz., the power of inhibition—which is the chief function of the cerebral cortex. No action can take place without a motive or some appropriate thought to suggest it, and every apparent excitation tends to an efferent impulse. It is the tendency of every sensorial stimulus to go out as action, but it is only when an erroneous or imagined perception or the memory of such a false perception becomes the motive to action and so influences conduct that a person so affected can be described as insane.

CONDUCT AND INSANITY.

It is conduct, not illusions, hallucinations, or delusions, which constitutes insanity. A person who sees mocking faces in the moon is suffering from an illusion; Pepper's Ghost and the Spirit of the Brocken are illusions; a pea on the tip of the fingers gives the illusion of a double object; the rapid revolution of a luminous object gives the impression of a continuous fiery circle; the ground rocking under foot after a sea voyage and a train moving out of the station (whilst one's own carriage is at a standstill) both give the illusion of movement; the stereoscope is an illusion, yet no one would state that the persons experiencing these illusions were for this reason and of necessity insane. We have in Holy Writ an example of visual illusions, for after the excessive drinking at the feast of Belshazzar the words, "Mene, mene, tekel, upharsin" were seen by one of the guests to be written on the wall of the great banqueting hall.

Dr. Johnson is said to have suffered from hallucinations, for he used to hear his mother's voice from Lichfield calling out "Sam," while he was in Pembroke College, Oxford. Hallucinations, nevertheless, are dangerous symptoms, for they force themselves upon the attention and they influence conduct. Aural hallucinations are often so relentless and so tyrannical and dominant that they not infrequently result in most dangerous acts of violence or destructive fury. The poet Cowper was himself distracted with delusions. He used to hear voices when waking in the morning, and he wrote "John Gilpin" during an attack of intense melancholia. The great Esquirol himself described how he saw "monks like cats capering about the monastery." Napoleon used to have interviews with a familiar spirit "in the form of a little red man," and he relates how he always saw his own star shining amid the starry hosts of the refulgent heavens before an engagement in the field. Joan of Arc, Peter the Great, and Warren Hastings are cited as names of persons of great mental power and yet who suffered from delusions, but who were not regarded as insane.

Insanity, which is the product of two factors—viz., stress and heredity—is no new disease. It was known before the Christian era, and was recognised and treated by the Egyptian priesthood 2000 years B.C. Biblical history relates in I. Samuel xxi., 13 and 14, how King David feigned madness in Gath—he "scrabbled on the doors of the gate, and let his spittle fall down upon his beard." Nebuchadnezzar suffered from insanity, yet after seven years of it he recovered and was replaced upon the throne of Babylon.

Races differ among themselves as to their liability to insanity, and it is suggested in text-books that the Jews are more prone to insanity than other races, and that the Teutons are less subject than are some of the Latin nations.

CLASSIFICATION OF INSANITY.

In considering the classification of insanity it would be most desirable if we could construct a scheme upon a psychological basis, reviewing in detail the affections of the different elements of mind. The varieties might thus be classified as disorders of perception, of memory, of the voluntary association of ideas, and of cognition or of judgment. Such, indeed, they are, but it has been found impossible to limit the varieties to any single process of mind. In mania the senses are all hyperacute, illusions and hallucinations abound, the judgment is impaired, and the will-power is affected. The mind acts when it does as a whole and no single mental process is disordered by itself. Only in immediate post-natal life is experience the result of a single sense impression, associations are soon formed, and any sensation becomes complex. A scheme of classification in order to be scientific should of necessity have a pathological basis, but hitherto the researches of chemistry and the investigations of the microscope have not availed us for this purpose. Therefore, if a classification is to serve a practical purpose it must be one based upon the symptoms presented, and which medical men are called upon to treat or to moderate. Such a classification is found to be not only convenient but also serviceable, and although scientifically inaccurate, it is nevertheless most useful for purposes of diagnosis and treatment, and for these reasons is the best hitherto proposed for our adoption.

We have therefore states of *mania*, which imply excessive action and excitement; loud, boisterous, restless conduct not infrequently accompanied with violence and general sensori-motor activity. *Melancholia* implies depression, personal unworthiness, and probably some suicidal tendency. *Dementia* is the tomb of the intellect, and the natural termination of many cases of mania and melancholia. In young people it may commence as such and proceed to complete incurability. Dementia implies loss of mind power, impairment of memory, indifference to personal habits, and often restlessness with destructive tendencies, and noisy, sleepless nights. Then there is insanity associated with epilepsy, with general paralysis, and also from brain tumours and arterio-sclerosis. Again, there is that vivid and distinct variety, without any definite loss of mental power, described as paranoia, the patient having fixed ideas and systematised delusions and suffering from what is technically called "chronic delusional insanity"—a perversion rather than a weakening of the normal mind. It is met with in those who, most often from a faulty heredity, may be described as eccentrics, oddities, cranks, monomaniacs, spiritualists, negative persons who object to vaccination, vivisection, the law of gravitation, or any effective agent for the comfort or betterment of man or the reverse. Although the X rays, marconigrams, the phonograph, the telephone, radio-activity, electricity, and chemistry have replaced the prophets, kings, and the priests of old, who worked their dreaded oracles upon the superstitious and the impressionable, we still find a harking back in search of the wonderful and mysterious to explain the meaning of hallucinations or the nature of insane delusions. This class of the insane seems to revert to a

time in the history of primitive man, when he was compelled, alone and single-handed, to combat the forces of Nature; when wind and rain, sea and flood, thunder and lightning were personified and had to be placated, when the ire of the gods had to be appeased, even at the expense of human sacrifice. These patients invent new and mysterious names to explain the influence of unseen agencies upon their bodies, and in their insanity they imagine these agencies to be pursuing them, to be influencing their lives or torturing them.

Conditions of insanity which alternate may be mentioned as demonstrating the rhythm occurring in Nature—excitement and depression alternate, action and reaction are equal and contrary, activity and repose succeed each other. Such forms are now accepted as "alternating" or "circular" insanity. Lastly, there are the congenital varieties, classified as idiocy and imbecility, which are teratological occurrences in Nature, and are not infrequently accompanied with perversions of the moral nature, hence the form moral imbecility brought prominently forward by the Royal Commission on the Feeble-minded. These moral freaks are often found in quite plausible and presentable children, who do well scholastically but who have no power of sustained effort, they "lie like truth," they are insensately cruel and wicked, they pinch and hurt other children, they torment animals, they hide and steal, and they are not infrequently perverted precociously in other ways.

The forms of mental disorder most prevalent to-day, however, are those primarily prone to attack young people. Esquirol described this condition as "acquired imbecility," others have described it under the more modern style of "dementia precox" or adolescent mania, stuporose insanity or primary dementia. It certainly occurs more frequently in my experience than it did years ago. Haslam, in 1798, refers to it as "a species of insanity sometimes occurring about the time of puberty; especially in those who have possessed a good capacity, a lively disposition, and in females more than in males. Their faculties are gradually obliterated until they are at last complete and incurable idiots." It seems to attack prematurely many of our most promising youths, generally or not infrequently the precocious and the brain-worker, rather than the manual labourer, and is to-day more often met with in young men rather than in young women. It is a variety of mental disease so incurable and chronic that it tends to fill our asylums with hopelessly insane patients. The report of the Commissioners in Lunacy also supports the assertion that it is more common now than formerly. These cases almost invariably commence in depression, and it is justifiable to believe, if we consider the form as associated mainly with the most vigorous period of growth, that the proportion has risen from 21·5 per cent. to 31·2 per cent. of all cases of insanity in 25 years. The chemical pathology of the disease worked out by Koch and Mann in Dr. Mott's laboratory is involved in some obscure auto-intoxication which causes an acute destruction of the nucleo-proteids and sulphur-containing substances—i.e., the phosphorised and sulphurised proteids undergo rapid dissolution. Microscopically the pyramidal cells show a deficiency both in number and in the amount of chromophilous substance, and there is an increase in the terminal stages of the glia tissue.

STATISTICS OF INSANITY.

Senile insanity, connected as it is with arterio-sclerosis and involution, shows the wreckage due to vascular lesions. It is characterised at its onset by giddiness and polyuria at night, and often is associated with cardiac and renal affections, and it certainly suggests the truth of the dismal aphorism "too old at 40," as the number of pre-senile cases admitted into our asylums in the last few years proves this form to be on the increase. Last year 1156 (551 males and 605 females) were received into the asylums of England and Wales. Senile insanity has increased from 11 to 20 per cent. in our asylums during a period of 15 years; 888 persons (380 males and 508 females) died during the year from changes accompanying senile decay. Possibly there may be some future control over these admissions through the Old Age Pensions Act, but it is yet too early to expect this.

Cases of insanity commencing in neurasthenia and psychasthenia are more frequently met with now than in the past. Last year's report of the Commissioners in Lunacy gives over 200 cases admitted into asylums in which these causes were given. Overstrain, over-fatigue, and over-excitement are responsible for much nervous disease. Mental stress is recorded to have caused insanity in 4410 persons (1902 males and 2508 females). These cases are an indication of excesses of many kinds and they reflect the accentuation of the struggle for existence in civilised countries, the effect of town life, the quest for pleasure, and probably also the marriage of the unfit. The prevention of this class is an immediate problem for the statesman. It is partly to be found in a more temperate life and certainly also in the compulsory notification of venereal diseases.

Syphilis is reported to be an associated factor in the causation of insanity in 850 males and 153 females, according to the statistics of the Commissioners in Lunacy; and general paralysis of the insane (closely related to these cases are those of tabes, which are not infrequent in asylums), a form of mental and bodily ailment closely connected, probably as cause and effect, with syphilis, was responsible for 1512 persons (1281 males and 231 females) admitted into asylums for the insane in England and Wales. I am certain that persons indulging in alcohol to excess and who have contracted syphilis are more liable to general paralysis after head injuries. Such causes as stress or worry act more readily as the "last straw," and these cases are not infrequent in the law courts, the friends appealing for compensation. I am very loth to put down officially as a definitely ascertained factor of causation the occurrence of a head injury, because not infrequently the patient has temporarily recovered and worked after the accident, and such a record would probably multiply cases of appeal for compensation, but a note is made of the fact unofficially in our case-books.

Cases of insanity associated with alcohol show no diminution in their incidence, for 2446 men and 992 women of this class were admitted into the asylums of England and Wales last year—a proportion of 23·3 per cent. males and 8·9 per cent. females on all cases admitted. Epilepsy is a frequent factor in the admissions; 7 per cent. of the men and 5 per cent. of the women admitted were the proportions recorded in the last Blue-book. It is interesting to note that insanity after surgical operations appears to be on the increase. Last year 106 (39 males and 67 females) were stated in the report of the Commissioners in Lunacy as having been admitted into asylums from this cause. Whether from shock or the anæsthetic, or whether the condition which the operation relieved was the cause of insanity is not stated.

Heart disease, morbid conditions of the blood-vessels, and definite arterio-sclerosis are reported in the last Blue-book to have been registered as causing death in a total of 1655 persons (715 males and 940 females). It is also interesting to note that cardio-vascular conditions and renal disease were responsible as a factor in the causation of insanity in 837 persons (425 males and 412 females); and 459 persons (176 males and 283 females) were reported to have died in asylums from renal disease within the year.

The influenza bacillus as a nerve toxin is, in my opinion, next in importance to the treponema pallidum as a specific cause of insanity; 568 cases (290 males and 278 females) were reported as occurring after influenza in the last official report. Tuberculosis figures as a proximate or a predisposing cause in 183 persons (98 males and 85 females), whereas 1332 (617 males and 715 females) died during the year, showing the high mortality from tubercle in asylums for the insane. 25 persons who were insane died from diabetes mellitus. The number of patients suffering on admission from glycosuria is also not inconsiderable. In 969 consecutive female admissions into the Claybury Asylum whose record was published by me in the *Journal of Mental Science* for January, 1906, a proportion of 2·5 per cent. was shown to have had this condition of the urine on admission. Goitre is occasionally found associated with insanity, the mental symptoms being a confusional delirium with excitement, often proving fatal.

Migraine and headaches are frequently met with, and mainly among epileptic patients, and eye-strain is not infrequently seen associated with early presbyopia. Skin diseases (eczema, pruritus, and psoriasis) are also found as associated factors in the causation of insanity. In one case, a girl with leprosy, the disease disfigured her face, and this so preyed upon her mind that she became insane and had to be brought into Claybury in consequence. A number of patients with drug habit are admitted into asylums for the insane, mostly

from morphia; but opium, chloroform, chlorodyne, cocaine, Indian hemp, and also veronal are indulged in to soothe mental pain, and eventually cause a complete mental breakdown. This is not the place to refer to the necessity for sleep, which to the over-wrought brain is as urgent a necessity as is food for the body, but insomnia is associated with most of the symptoms which presage early insanity, and in not a few cases timely sleep has warded off an otherwise inevitable mental breakdown.

THE ADMINISTRATION OF THE PUBLIC HEALTH AND EDUCATION ACTS IN RELATION TO THE PREVENTION AND CURE OF DISEASES OF THE THROAT AND NOSE.

BY T. JEFFERSON FAULDER, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE; CHIEF ASSISTANT, THROAT DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, ETC.

(From the London School of Economics.)

IN the Education (Vacation Schools and Medical Inspection) Act, 1907, it is stated that the powers and duties of a local education authority under Part III. of the Education Act, 1902, shall include the duty to provide for the medical inspection of children before or at the time[1] of their admission to a public elementary school, and on such other occasions as the Board of Education direct, and the power to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children educated in public elementary schools. The antithesis of the words "duty" and "power" is notable.[2] The former is relatively simple, the latter leads to all sorts of difficulties. In pursuance of the enactment the Board of Education[3] issues to the authorities concerned various memoranda containing instructions and suggestions and recommendations.

We may assume that, the principle of compulsory free education being long ago admitted, the medical inspection and possibly treatment of the children is a necessary corollary. Some part of the State wealth of England spent on education is wasted unless the children are in a condition to take full advantage of it.[4] Presumably economic principles, not primarily philanthropy, are at the basis of this legislation. It can only be regarded as absurd[5] to expend an elaborate educational system on a child deaf from any cause or visually defective or otherwise incapacitated. The health of the child is the health of the nation's workers,[6] and it is therefore at least as important as education. Education has been made compulsory, and its processes are subject to inspection by central authority. As the practical value of education depends to a large extent on the health of the recipient, there is no apparent reason why health should be left to take its chance.

How far school inspection is required, what necessity there is for it, what advantageous results may be expected from it, are questions capable of solution now, before the full effects of the Act of 1907 are realised. It is often said that mere inspection is useless, and this is no doubt true to a very great extent. Large masses of information and statistics are collected, and if these are relegated to store-rooms and oblivion we may well say "*cui bono?*"[7] The full benefit of a system[8] of school inspection can only be obtained if treatment, curative and preventive, is by some means associated with it. By far the most important aspect of the whole question is that of prevention,[9] and there can be little doubt that preventive medicine is the medicine of the future. Some diseases are obviously preventable, others are known by medical men to be preventable, whilst of the rest some at any rate are probably preventable. Much valuable work has been done in the way of prevention by the Public Health service, by the Poor-law service, and by workers on tropical diseases. Their work upon the whole deals with large questions of hygiene, sanitation, isolation, and so forth. When we isolate successfully a person suffering from diphtheria we prevent an epidemic of that disease. When we inoculate such a person with anti-diphtheritic serum we prevent the disease from running its usual course. This latter is an instance of preventive medicine applied to the individual. Preventive medicine in this latter individual sense is now made possible on a large scale by the Act for the medical inspection of schools, and this in an unknown number of directions.[10] But there is this serious difficulty. The people are not at all interested in prevention, and they value health most when they have lost it. Communities are, or were, very much afraid of epidemics of dangerous infective diseases, but to the processes by which these have been abolished or diminished they pay small heed. The same people who are much excited by an adjacent case of small-pox will not so much as notice an army of mouth-breathers or a number of discharging ears. Yet it takes very little consideration to decide whether small-pox or disease of the ears does the greatest amount of damage.

The general ignorance about matters of health and hygiene[11] is profound. Of late years things medical and surgical are more and more freely discussed in the lay press, but upon the whole the ideas which the public have in this way acquired are worse than useless. The same remark might be applied to the hosts of advertisements of infallible nostrums, of various appliances and methods of cure which are each day scattered broadcast over the country.[12] Thrilling descriptions of narrow escapes from death, disease, or disfigurement by aid of this or that potation do little to further the cause of preventive medicine. The blame cannot, however, be laid entirely at the doors of the people. The medical profession as a whole leaves undone that which ought to be done. Yet it is in a vicious circle and cannot help itself. It has to supply the public with what the public thinks it wants. Thus no medical man does or can practise preventive medicine to its full extent unless he be a member of the public services, and under existing conditions it is not in the interest of ordinary doctors to prevent disease. There is some substratum of truth in the aged jest about him who was saved from ruin by an epidemic of small-pox or influenza.

People have great difficulty in realising the possibility of disease[13] until they are in its grip, with the mischief more or less fully done. Assuming the value of inoculation against small-pox, it is almost certain that no one individual would realise this value in his single isolated case unless forced upon him by an attack of the disease. But if during an epidemic he sees that in a vaccinated community the mortality amongst infants is *nil*, whilst in a community unvaccinated the infant mortality is 50 per cent., then the whole affair comes to wear a different appearance in his mind. Prevention as applied to communities has thus acquired a relatively strong position, while prevention as applied to the individual is still in a most rudimentary state. Another difficulty arises from the fact that the sources of ill health or of defective physique are often remote. We may now consider some of the effects which are produced or supposed to be produced by disease in the throats of children.[14]

1. *Nasal Obstruction.*

It is clear that a sufficient mass of growth (adenoids) at the back of the nose will abolish nasal respiration. Under these circumstances the tissues lining the nose cannot perform their proper functions of warming, moistening, and purifying the inspired air. These tissues consequently become unhealthy and, so to say, paralysed from disuse; they are relaxed and swollen, their secretions collect, and we get a suitable field for the growth of numerous kinds of bacteria, not all of them innocuous. The local circulation is deprived of its normal natural stimulus,[15] and this in a growing child is a most important event, because interference with the circulation must interfere to a greater or less extent with the normal growth of the parts, including the skeleton. In the same manner a limb disused from childhood fails to grow to its normal form or size. Nasal obstruction, however produced, may have various consequences in its turn besides those mentioned.

2. *Mouth Breathing.*

For some unexplained causes habitual mouth-breathing is frequent among civilised races at all ages. It is very common among children. It attracts very little attention. It does not occur at all among the lower animals. One wonders if much comment would be made if every second or third animal seen in the street had its mouth open. Anyone who suffers from nasal obstruction must obviously breathe through the mouth, and the mucous membrane of the mouth must necessarily do its best to perform the functions of the nasal mucous membrane. For this it is but poorly adapted and suffers accordingly. Everyone knows the dry mouth which results from a common "cold in the head," especially during sleep. Children who are habitual mouth-breathers[16] are liable to affections of the throat like tonsillitis, to certain affections of the larynx, and also to diseases of the lungs.[17]

The tissues of the throat of a child[18] are in a state of growth and transition, and are very amenable to adverse conditions. There is no doubt that this is one of the ways in which chronic enlargement of the tonsils is produced. Young children[19] are apt, in spite of some degree of nasal obstruction, to persist in attempting to maintain nasal respiration during sleep. It follows in such cases that the air entry is inadequate, the lungs do not expand properly, and the foundations of chest deformities, such as "pigeon breast," are laid. Sooner or later the habit of mouth breathing is acquired, and once acquired is not easily unlearned, even though an original cause such as "adenoids" be removed or, as happens in the course of time, disappears spontaneously.

Two other instances of this kind of loss of physiological function may be mentioned in illustration. When a child has worn a tracheotomy tube—e.g., for diphtheria—for any length of time, there is sometimes considerable difficulty in dispensing with the tube even though the obstruction is quite removed. Such a child has apparently lost the proper use of the vocal cords.

The second illustration has reference to the nostrils or "alæ nasi" which on forcible inspiration ought to expand. If a simple mouth-breather be directed to close the mouth and take a deep breath through the nose it is not at all uncommon to see the nostrils immediately collapse, and this in spite of the fact that they are under the control of the will.

3. *Deafness.*[20]

Under conditions of sound health the air and whatever it may convey have no access to the internal ear except by way of the nose or throat. It is therefore likely that diseases of the ear[21] are to a great extent dependent on diseases of the throat and nose. To begin with, the internal ear requires ventilation. This may be abolished by the presence of adenoid overgrowths, not necessarily of such a size as to cause any appreciable amount of nasal obstruction. The result is interference with the delicate mechanism of the ear, and hence some degree of deafness. These conditions continuing, the ear itself becomes unhealthy and the deafness increases. Such an ear is also more liable to various forms of inflammation and infection, all serious, some highly dangerous. It is said—and the statement is certainly correct—that a child with adenoids who contracts measles or scarlet fever is more liable than another to serious disease of the ear as a complication. Disease of the ear is a very serious thing from the point of view of education and the national capital in efficiency.

4. *Defective Intelligence.*[22]

The classical picture of what is called the "typical adenoid facies" is well known. Numerous medical books give illustrations showing the vacant, expressionless face, the open mouth, the projecting upper teeth, the dull eye, the wide bridge and pinched nostrils which are characteristic. But this "typical case" is, like many other "typical" cases in medical literature, comparatively rare. Adenoids are not necessarily associated with stupidity. Particularly bright children may suffer from them. But equally so may pronounced idiots. Doubtless many children are considered to be dull or stupid when they are only in reality slightly deaf. But deafness during the growing period of life, and especially during school life, cannot but have a deleterious effect upon the intelligence. The bright, clever child will be handicapped, the naturally dull child will be rendered more dull, because education consists partly in impressions acquired by way of the special senses, of which hearing is not the least important. Hearing, as we have seen, can be interfered with by adenoids.

5. *Diseases of Glands.*

The mucous membranes of the throat and nose are "drained" by the lymphatic system into definite groups or chains of lymphatic glands situated in the neck. As a matter of fact, a very large proportion of children whose throats are unhealthy do have palpably enlarged glands in the neck. Palpable enlargement of these glands is undoubtedly pathological and is often not curable by simple means, even when its cause is removed. Thus in some cases abscesses develop and in others the glands become tuberculous.

As regards tuberculosis, there is from time to time much discussion as to the route by which the bacillus gains access to the system, and much clinical and experimental work has been done upon this subject by various observers. Some favour the gastro-intestinal route, others the respiratory. It appears unnecessary to labour the point here in view of the well-known fact that the tubercle bacillus can penetrate a mucous membrane leaving no trace of its passage and only producing its customary effects in the parts beyond, as, for example, in the present case, in lymphatic glands. Moreover, numerous observers[23] from time to time have reported the actual finding of tubercle bacilli in the tissue of the growths called tonsils and adenoids.

6. *Effects on the Skeleton and on Growth.*[24]

Deficient aeration, even if the air supplied to the breather be of the best, must result in defective growth. If the air be vitiated the results in this direction must be more pronounced. Mechanical effects of deficient air entry upon a growing child are various kinds of deformity of chest, spine, and abdomen. Such are "pigeon breast" already alluded to above, "Harrison's sulcus," "barrel chest," curvatures of the spine, &c. Incidentally it must be noted that these deformities predispose to pneumonia, bronchitis, phthisis,[25] and other diseases of the respiratory apparatus. There has been much discussion as to the etiology of certain deformities of the jaws,[26] of the teeth, and of the nasal skeleton. Some authors, for instance, question their causal relationship with "adenoids" and nasal obstruction.

The deformities here meant are:—(*a*) Upper jaw:[27] Narrowing or compression from side to side; projection of the anterior part; and high-arched and V-shaped palate.[28] (*b*) Teeth: Overcrowding and malposition, irregularity

and projection of upper central incisors. (*c*) Nose: Deviations and irregularities of septum; and defective growth of other nasal bones.

The "typical" adenoid case will always be found to show some or all of these deformities. Naturally, they take a long time to develop, and their development coincides with the period of the second dentition. Consequently they are observed with increasing frequency towards the later years of childhood—that is to say, a period during which "adenoids" tend to disappear. Therefore the relation of "adenoids" to the deformities in question may be incapable of absolute proof. But the association of adenoids, nasal obstruction, and mouth-breathing in early childhood with the presence of these deformities at puberty or in later life[29] is too frequent to allow of its being neglected.

7. *Infective fevers.*[30]

Many of these affect the throat either primarily or secondarily. In many of them the specific microbic poison attacks the patient by way of the mucous membranes of the throat[31] or nose, as in the case of scarlet fever, measles, diphtheria,[32] rheumatism,[33] and influenza.[34] Pettenkofer's requirements for a specific infection are—(*a*) the infecting agent; (*b*) receptivity of the individual; and (*c*) conditions of environment. The second of these factors, the receptivity of the individual, is increased by, amongst other things, unsound states of the throat.[35]

Scarlet fever.[36]—In this disease the infection usually takes place by the mouth or nose. The greatest susceptibility occurs at the age of 5 years, after which liability to infection gradually diminishes. Infection is most likely to occur after some other throat affection. The mortality of scarlet fever diminishes from 1 to 25 years of age. It would therefore seem desirable to protect children from this disease.

Measles.—This disease is extremely infective. It is infective in its earliest stages—that is, before there are definite symptoms such as the characteristic rash. It is therefore difficult to check. Here, also, the state of the health has a great influence on the "receptivity." Illnesses of a catarrhal sort like bronchitis and relaxed mucous membranes, such as occur commonly in rickets, are predisposing causes. It seems that very young children up to the age of 6 months are the least susceptible. Three-fourths of those who die are under five years, seven-eighths are under ten years. The mortality of measles is fully twice as great as that from scarlet fever.

Diphtheria.—Children in the first five years of life are most subject to this disease, which is more serious in them than in adults. They are rendered liable to an attack by unsound states of the throat, and convalescents from scarlet fever, measles, whooping-cough, and from simple sore-throat are very susceptible. Nasal diphtheria is often not recognised and is therefore dangerous.

In connexion with these specific fevers mention must be made of what are now known as "carrier cases"[37]—that is to say, persons who, without suffering themselves, are yet capable of infecting others. Diphtheria is the best example to give because the specific germ of diphtheria is known and can be recognised.

It has been said above that unsound states of the throat predispose to these infectious fevers. Now as regards adenoid growths, it is not pretended that they in all cases constitute an "unsound state." A certain amount of "adenoid" tissue is normal and is widespread in the throats of children. But the local over-growths called "adenoid vegetations," when they cause any of the effects mentioned above, must be held to constitute an unsound state. It is thus possible to construct a rather terrible genealogical tree[38] of diseases and affections having their origin in the nose and throat of children. Many of these affections persist throughout life as a handicap to the individual and a loss to the State.

Medical inspection of schools has been applied in many countries and places[39] before it became compulsory in England, and reference may with advantage be made to some of the results.

1. *Berlin.*—In a report furnished by Professor Dr. A. Hartmann to the Berlin School Board for the year 1905–06 we find that 32,902 candidates for admission to the schools were examined. Of these, 3056 were rejected; 7355 were placed under special medical supervision. Among the causes for rejection or for medical supervision we find:—

	Rejection.	Supervision.
Disease of nose or throat	24	 904
Disease of ear	41	 712

Out of a total of 225,237 children 29,622 were under special medical supervision.

Disease of nose or throat	2107
Disease of ear	3001

2. *Belgium.*—In the *Revue d'Hygiène* for April, 1906, appears an article by Dr. Ensch (of the Belgian public health service), who is a great enthusiast for preventive medicine. He examined 6729 pupils with reference to the condition of their ears and as a result give the following table:—

One Ear Affected.

Percentage.	Age.	Percentage	Age.
15·2	6– 7 years.	14·71	10–11 years.
16·0	7– 8 ,,	15·77	11–12 ,,
22·36	8– 9 ,,	14·13	12–13 ,,
17·29	9–10 ,,	13·69	13–14 ,,

Both Ears Affected.

Percentage.	Age.	Percentage.	Age.
6·45	6– 7 years.	6·35	10–11 years.
6·97	7– 8 ,,	6·98	11–12 ,,
8·52	8– 9 ,,	5·09	12–13 ,,
7·02	9–10 ,,	5·94	13–14 ,,

As Dr. Ensch very properly remarks, it appears that at the age of 6 many ears are already damaged.

3. *Tasmania.*—A report issued by the Department of Public Health, Tasmania, in October, 1906, on the results of a medical examination of over 1200 children attending State schools in Hobart. This is a very important publication, as are all those which are so far available on the subject of school inspection. A few paragraphs may be quoted. Page 7.—A frequent association of flat chest, pigeon breast, and transverse contraction with pronounced adenoid growths was very noticeable and agrees with the conclusions of Garry Simpson and other observers elsewhere. Page 13.—Of 1272 children 155 = 12·17 per cent. had defective hearing or disease of the ear. "The prevalence of ear defects in the extent found is a serious matter, and one which can be satisfactorily dealt with only by medical inspection. Their frequent association with adenoid growths was rendered very clear during the examination."

As regards adenoid growths and enlarged tonsils, the author estimates a percentage of 33, or 403 out of the 1272 children examined. The diagnosis was made on subjective evidence alone, but Dr. Elkington allowed for a possibility of one-third error, and the tests used were very stringent. It is important to note that of the 133 children placed by the teachers in the "Dull or Defective" group 79·7 per cent. are returned as having adenoids or much enlarged tonsils; and further, a definite connexion is shown to exist between mental dulness and defective organs of sight and hearing.

Further comments are as follows: Page 14.—"The child is rendered particularly liable to infection by diphtheria, consumption, and other serious diseases, and perforation of the ear-drum with consequent permanent deafness or dangerous disease of the mastoid cells is an almost invariable consequence of measles or scarlet fever occurring in such a subject." "A child with marked adenoid growths is practically useless for educational purposes." "Had a system of medical inspection no further result than to induce the parents of 20 per cent. of the children suffering from this mental and physical handicap to submit them to

[39] THE LANCET, vol. i., 1907, pp. 1046, 1123, 1261, 1398, 1817, and 1819, and vol. ii., p. 543. Cf. also Dr. J. M. Martin, medical officer of health of Gloucestershire, Memorandum on the Report of the Inter-departmental Committee on Medical Inspection.

operation, it would amply justify its existence from an economical point of view."

4. *Dundee.*—Report of the Dundee Social Union, 1905. In the introductory medical report (p. 99) by Dr. Charles Templeman, medical officer of health, it is stated that the dull and defective children in Dundee amount to 9·9 per cent., and that in a large proportion of these cases the condition is due to physical defects which are remediable. Page 100.—Dr. G. T. Guild's report on ears shows that in Dundee the hearing was normal in only 55·15 per cent. of the children. "The most common cause of this defect was the presence of adenoid growths in the pharynx which was found in 19·9 per cent. of those in the Dundee children examined." Page 101.—"The marked effect of this (adenoids) on the physical and mental condition of children has long been observed. They frequently lead to deformity of the chest and to mental dulness." Page 102.—The preliminary report concludes as follows: "When it is borne in mind that in a large number of school children such defects are often unsuspected by the most careful parents, and that many of them are easily remedied in youth, which if neglected may seriously handicap the child throughout the whole of his future life, I think that the results of the examination of the Dundee school children materially adds to the mass of evidence already accumulated showing the urgent necessity for the compulsory medical inspection of school children." Page 116.—Report on nose, throat, and ears by Dr. Guild: "The examination of the conditions present in the nose, throat, and ears of 787 children in the Board Schools of Dundee shows that these practically receive no attention." "The majority of cases of intra-nasal obstruction (20) and those of adenoid enlargement (216) require treatment." "Those children who are frequently absent from school with sore throats were found almost invariably to be mouth-breathers or the subjects of enlarged tonsils. This loss of time, which must interfere with their attendance, ought to be prevented. Treatment was required in the majority of the 136 cases of tonsillar enlargement." "As tested by the watch, an alarming amount of deafness was detected, but when combined with other examinations much of it was found to be of a temporary character and not likely to become permanent; if the examination had been undertaken in summer there would have been less of it. But apart from this, in a large percentage of cases deafness of a more permanent character was detected. This was largely due to extension of catarrh from the nasal passages usually associated with adenoids or enlarged tonsils." Page 117.—"Sixteen cases of chronic suppuration of the middle ear were detected. The children were receiving no suitable treatment and ran the risk of permanent deafness or of disease imperilling their lives." "The result (of neglect) is that hundreds of school children in the Board Schools of Dundee are growing up with more or less damaged hearing, which, if taken in time, would be curable, but for want of this becomes permanent, and which must seriously damage their prospects in after life."

I have made a table from the Dundee details to show the relation between dull and defective children and affections of nose, throat, and ear:—

—	No. of cases.	Marked deafness with adenoids.	Slight deafness with adenoids.	Slight deafness.	Marked deafness with chronic suppuration.	Tonsils.	Various (e.g., wax).	Percentage showing disease.
Dull	87	17	5	9	11	7	6	63
Defective	9	2	0	0	1	0	6	100

5. *Leith.*—1906. Report on 806 school children by Dr. William Robertson, medical officer of health of Leith. Page 21.—"Excluding decay of the teeth, where a very small minority were unaffected (and also enlargements of the neck glands), it was found that out of the 806 children only 218 were without defect of any kind." In the list of defects occur the following: Affections of nose and throat, 426 = 52·85 per cent.; ear disease and deafness, 91 = 11·17 per cent.

6. *Dunfermline.*—First annual report on the medical inspection of school children in Dunfermline, 1906, by Dr. R. C. V. Ash. 2000 children of all ages were examined. Page 21.—Diseases of nose, ear, and throat. "Among 1500 boys examined, 66, or 4·4 per cent., showed evidences of adenoids. Most of the cases occurred among the younger children." Page 22.—"Among the ultimate results of adenoids are changes in the form of the chest, deficient aeration of the blood with its attendant effects on the general condition, a liability to repeated bronchial catarrhs, changes in the facial appearance, giving a dull, stupid look, and complications in the ears which may end in permanent deafness." "There is a very prevalent ignorance on this question of adenoids, and a consequent apathy as to its effects amongst the majority of the parents." Page 22.—Ears: 52 cases of purulent discharge from the ears were found = 3·5 per cent. of the total examined. Many of the cases had been suffering from this condition for very long periods, and treatment had been sought in only a small proportion. As in the case of adenoids, apathy with regard to this condition of the ears is general, yet the possibilities for serious results are even greater than with adenoids. At the least, permanent injury to the sense of hearing must follow continued neglect. Page 23.—Table of diseases of nose, ear, and throat in 1500 boys:—

		461

7. *Edinburgh.*—City of Edinburgh Charity Organisation Society: Report on the physical condition of 1400 school children in the city of Edinburgh (1906). Page 38.—Table XV., nose and throat. 1358 children had the nose and throat carefully examined by Dr. J. M. Farquharson and Dr. J. D. Lithgow, and a large and varied series of pathological conditions were found. "Throat conditions.—Though the examinations of nose and throat were made at the same time, it will be advantageous to separate the remarks made. The conditions in the throat that call for chief comment are enlarged tonsils and adenoids. Their detection and removal are of vital importance to children of school age. To a certain extent they probably always occur together, but in some cases either the enlarged tonsils or the adenoids are not specially marked, and accordingly the children are conveniently divided into three groups: (*a*) where there were enlarged tonsils only; (*b*) where both enlarged tonsils and adenoids were present; and (*c*) where adenoids alone were present. 192 children, or 14·14 per cent., had enlarged tonsils; 109 children, or 8·03 per cent., had both enlarged tonsils and adenoids; and 92 children, or 6·77 per cent., had adenoids only. Out of these 393 children 221 were boys and 172 were girls. It is probably true that in time (after they have reached the age of puberty or later), in most of these children the conditions would disappear, but in the meantime their effect on the child's general health and his position in school is too serious to allow of this waiting. Children with these troubles suffer in their general health. Their respiration is impaired and insufficient, and chest development is interfered with. Muscular development is apt to be poor, and such children are more liable than others to inflamed throats, deafness, and bronchial troubles, all of which tend to frequent absence from school. Mentally, too, they are deficient. They lack concentration in their work and power of application, and invariably fall behind others of the same age. All children in a school that are at all backward should have their throats examined for the presence of these conditions." Page 39.—"Altogether 42·49 per cent. of the children were the victims of some unhealthy condition of the throat and nose, all of them probably requiring attention, and by their removal the fitness of the children for their work at school would be much improved."

8. *London.*—Annual reports on the medical inspection of school children are issued by the London County Council (Dr. James Kerr.)

(To be continued.)

SOME OBSERVATIONS ON GASTRO-INTESTINAL FERMENTATION.[1]

BY DAVID SOMMERVILLE, B.A., M.D. R.U.I., M.R.C.P. LOND.,

HONORARY PHYSICIAN, FARRINGDON GENERAL DISPENSARY; HONORARY PHYSICIAN AND PATHOLOGIST, LONDON SKIN HOSPITAL.

THERE are two types of bacterial fermentation met with in the alimentary canal: (1) an acid fermentation in the upper part, and (2) an alkaline or putrefactive fermentation in the lower part. Investigation of these biochemical activities demands some accurate knowledge of biological chemistry and bacteriology. But an intelligent grasp of the matter may be obtained with a much less profound knowledge of these subjects than the average general practitioner of medicine is inclined to admit.

In dealing with gastric contents, fæces, and urine, chemically and bacteriologically, no very complex apparatus is required, and with a brief preliminary training any practitioner possessing the instinct of research may in a very few years acquire the power of perceiving, in many of the chronic gastro-intestinal conditions coming before him daily, order—pathological order if you will—where before he saw nothing but chaos. At the moment considerable attention is being directed to the use of various preparations of lactic-acid-producing bacilli, the object of which is to so increase the quantity of lactic acid in the gut that the organisms producing alkaline putrefaction may be destroyed. Metchnikoff and Cohendy, working with the human subject, showed that certain lactic-acid bacilli retain their vitality whilst passing through the digestive tract, and can finally be cultivated from the fæces.

It has long been known that where an individual consumes excessive quantities of protein—i.e., larger quantities than he can assimilate and finally oxidise—a more or less definite set of symptoms appears characterised by headache, drowsiness, lassitude, and irritability; these symptoms are accompanied by an increase in the ratio of ethereal to preformed sulphates in the urine, as also an increase of the same sulphates to the total nitrogen (Amann's coefficient). Such a urine when subjected to a simple qualitative examination gives increased quantities of indol, indolacetic acid, phenol, skatol, and aromatic oxyacids, all products of intestinal putrefaction. The fæces of such a patient when distilled and the distillate shaken up with a concentrated solution of mercuric chloride (Schmidt's reaction) yield the red colour changing to yellow fluorescence indicative of hydrobilirubin, an index of reduction processes due to putrefactive bacteria. In this connexion it may be noted that the variations in amounts of indol and phenol and their derivatives excreted in the urine and fæces form a fairly accurate index of the degree of putrefaction going on in the intestine, since these substances are not formed in any other part of the body, nor through any other agency than that of putrefactive bacteria. This statement excludes, of course, any degree of putrefaction that may have been present in the protein food before ingestion. In health the amount of ethereal sulphates varies uniformly with the amount of protein consumed, and their ratio to the total nitrogen in the urine is approximately constant—viz., about 1·5 : 100. If carbohydrate be substituted for protein in the diet of such a patient, his physical and psychical attitudes towards men and things become quite changed. He loses his headache, becomes alert, and exchanges his irritability and moroseness for a more agreeable manner. Indol, indolacetic acid, and the aromatic oxyacids rapidly decrease and in time completely disappear from his urine, whilst his hard dark brown and extremely offensive fæces give place at first to loose, but afterwards to formed soft grey and inoffensive material. Ethereal sulphates are always markedly reduced on milk diet, and the richer the milk in sugar the more marked the reduction.

The first systematic investigation of the bacteria of the fæces was made by Escherich ("Die Darmbakterien," Stuttgart, 1888). By simple aerobic and anaerobic methods he isolated from the fæces of nurslings and bottle-fed infants some of the best known intestinal bacteria. Since then many organisms have been imperfectly described and incompletely identified. Attention has been diverted from the normal intestinal bacteria by work on the specific organisms of typhoid, cholera, and dysentery.

Whilst it is impossible and unnecessary to attempt an individual study of the millions of bacteria discharged daily in the fæces, it is comparatively easy and highly instructive to study fæcal bacteria tinctorially and morphologically as positive and negative Gram-staining bacilli; and chemically as acid producers and alkaline-putrefaction producers. Bacilli predominate largely over cocci in the fæces. The most important fact perhaps to the practical physician engaged in this study is that definite relations exist between the nature of the diet and the leading characters of the resulting bacteria, including the products of their vital activities. Sharp alterations of diet are followed by rapid changes in the types of bacteria.

The dominant type of organism in the fæces of the bottle-fed infant is the Gram-negative B. coli. If carbohydrate, say lactose, be freely used in the food of such an infant for a few days, acid fæces—perhaps diarrhœa—the result of Gram-positive acid-forming bacteria, will follow almost immediately. Tissier's Gram-positive B. bifidus is now recognised by all who have worked at the subject as the dominant organism in the fæces of healthy nurslings. In adult life when B. coli is accompanied by putrefactive anaerobes, such as Bienstock's B. putrificus, and Welch's B. aerogenes capsulatus, the ethereal sulphates, which in infancy and early childhood were *nil*, form the proportion of 1 : 12 or 1 : 8 of preformed sulphates in the urine. In old age Welch's organism is perhaps the most important intestinal putrefactive agent and is responsible for much of the protein cleavage found in the colon, the resulting phenols, which are always easily and rapidly absorbed from fæces, accounting in large measure for the accompanying muscular weakness and mental depression.

I have pointed out elsewhere that during the transformation of nitrogenous organic matter, as seen in the purification of sewage, as the various progressive stages of the operation are observed, a corresponding change is seen in the type of micro-organism engaged, until in the end of the operation the organisms are as wholly different from those of the commencement as is the resulting chemical substance in the form of nitric acid from raw protein. The chemistry of the putrefaction of proteins in the alimentary canal of man runs on remarkably similar lines to that of putrefactive fermentation in sewage. And the conclusion of the matter seems to be that the type (and consequently the characters of the bacteria) found at any stage of either of these parallel processes is determined by the chemical constitution of the foodstuffs available at that particular stage. More than ten years' work at the chemistry and bacteriology of fæces has taught me that any real assistance which can be offered to the patient suffering from acid fermentation of the upper tract, or alkaline and putrefactive fermentation of the lower, must be in the form of intelligently chosen foodstuffs rather than drugs.

In such gastric conditions as hypochlorhydria, achylia gastrica, atony, incontinence of pylorus, and most cases of so-called neurasthenia, putrefactive fermentation will invariably be found in the colon if looked for, and one is forced to the conclusion that in many, if not in all, cases the latter is the primary ailment and that the gastric condition is secondary. In a large number of cases of pronounced dilatation of the stomach putrefactive fermentation is found in that organ as well as in the great bowel, and in studying the microscopic fields of stained specimens of the gastric contents, as also the cultural characters of the micro-organisms present, a striking similarity to the organisms of the colon becomes at once apparent.

It is impossible in the time at my disposal to do more than mention the methods one employs in dealing with bowel contents and urine. In my cases of suspected gastric dilatation a tracing of the outline of the organ is made on the X ray screen, whilst the patient in the standing position swallows an emulsion of two ounces of bismuth subnitrate in milk; this outline is afterwards transferred to tracing paper. The information afforded by this simple procedure is definite and frequently enables one to forego the otherwise unpleasant duty of passing the gastric tube. Where the

[1] Abstract of a paper read before the Aldershot Medical Society.

gastric contents must be examined it will often be found that a qualitative test for HCl by the silver method in a few cubic centimetres of the filtered contents is all that is necessary. Where HCl is absent one hour after partaking of a meal it is only waste of energy searching for lactic and butyric acids. A few cubic centimetres of the neutral (sometimes alkaline) gastric contents are filtered and inoculated into gelatin; in most cases of chronic dilatation proteolytic digestion will be thoroughly established at the end of from 48 to 72 hours at 20°–22° C., or in a longer period at lower temperatures, indicating the presence of putrefactive bacteria, and putrefactive bacteria which are not obligate anaerobes.

In dealing with fæces account is taken of total weight in the fresh and dry conditions, colour, consistency, and reaction. Schmidt's reaction for hydrobilirubin when positive indicates putrefactive bacteria, and the test with Millon's reagent for aromatic oxyacids when positive confirms this indication. In urine I prefer Obermeyer's test for indican and the application of nitrites for indol-acetic acid. Determination of the ratio of ethereal sulphates to preformed sulphates and also to total nitrogen is most important at the commencement and throughout the entire period of treatment, as with a little experience one can learn, apart from bacteriology, whether, and how much, the putrefactive bacteria are increasing or decreasing. Total N is best effected by the Kjeldahl-Gunning method. The study of fæces bacteriologically for purposes of controlling putrefaction need not go beyond the microscopical examination of Gram-stained smears, made from emulsions of finely ground fresh fæces in normal saline, and inoculations of these emulsions into glucose, lactose, and saccharose broths, acid glucose broth, and milk. This simple procedure will enable the careful observer to distinguish the dominant members of the putrefactive or protein flora from the dominant members of the acid-forming or carbohydrate flora.

In a typical case of putrefaction a Gram-stained smear presents in a large number of small areas of the field long thick bacilli with round ends, stained positive, a less number of shorter bacilli with round ends, also stained positive, and a multitude of Gram-negative small bacilli, probably B. coli. Inoculation of a small quantity of emulsion of fresh fæces into the above media produces large volumes of gas, much turbidity, and, finally, a sediment at the bottom of the tube rich in the same Gram-positive bacilli. Inoculation into milk gives large quantities of gas and peptonisation. Inoculation into acid glucose broth gives practically no growth indicating absence of acid-forming bacteria. When the protein diet of such a patient has been exchanged for carbohydrate and a period of from 14 to 21 days is allowed to pass, the prominent organisms are now found to be Gram-positive long bacilli much thinner and more evenly scattered over the field. Some of these are bifid, conforming morphologically to Tissier's B. bifidus, found in the fæces of the suckling. Culturally the conditions are the reverse of those of the putrefactive group associated with protein diet. In the milk tubes there may be slight coagulation, but no pronounced peptonisation or formation of free gas. The fermentation found in the upper part of the tract which results in the formation of lactic and butyric acids appears to be more complex than that in the colon, but the failure to digest starch with the associated formation of acids, CO_2, and CH_4, can be largely prevented by the substitution in these cases of proteins for insoluble carbohydrates. The ingestion of sugars in some of these cases is followed by much less gas production. As carbohydrates furnish the bulk of the kinetic energy of the body, and as patients who have suffered for a long time from acid fermentation possess but little of this, the physician must bear in mind that carbohydrates should not be cut off entirely for long periods together. It will be found extremely useful in some cases to substitute for starch a sugar—lactose, glucose, or saccharose—according to the particular type of the fermentation.[1]

In conclusion, I venture to affirm that in no field of practical medicine will the application of any science to troubles of the alimentary tract reward the physician more thoroughly than the application of the biochemical principles of fermentation.

Marylebone, W.

ON THE

HYPODERMIC AND INTRAMUSCULAR INOCULATION OF BACTERIAL VACCINES AS DEMONSTRATED BY EXPERIMENTS WITH TYPHOID VACCINE.

BY D. SEMPLE, M.D., M.CH. R.U.I., D.P.H. CAMB.,
LIEUTENANT-COLONEL, R.A.M.C. (RETD.); DIRECTOR, CENTRAL RESEARCH INSTITUTE, KASAULI, PUNJAB, INDIA.

THE administration of bacterial vaccines for prophylactic and therapeutic purposes is a duty which most medical men are nowadays called upon to carry out in the ordinary routine of their practice. A growing demand for these remedies has created the necessity for a correct knowledge of the best method of their administration.

We have ample evidence to prove that proper dosage and proper interspacing of doses are cardinal factors to be taken into account in the scientific administration of any bacterial vaccine; and we have also evidence to the effect that there are no great difficulties in arriving at correct information in regard to these two factors—viz., dosage and interspacing of doses. On the other hand, there seems to be some divergence of opinion as to the tissues of the body into which bacterial vaccines should be inoculated in order to produce the quickest and highest immunising response.

It is still a disputed point as to what particular class of cells or tissues of the body take part in the elaboration of antibodies after the inoculation of a suitable dose of any bacterial vaccine. We are now and again confronted with statements backed up by fairly convincing proof to the effect that antibodies are formed locally at the seat of inoculation, and that subcutaneous and intramuscular tissues are the tissues most concerned when inoculations are given into these regions. On the other hand, Metchnikoff and his followers would have us believe that the leucocytes are the prime agents in the elaboration of immune substances; several other workers, including Pfeiffer and Marx, also Ruffer and others, have carried out experiments which go to prove that the lymphoid organs, spleen and bone marrow, are situations where agglutinins are formed early after the inoculation of bacteria for immunising purposes.

Irrespective of what particular cells or tissues of the body take part in the formation of antibodies, there are practically only two situations where bacterial vaccines can be conveniently given in the case of man—viz., either subcutaneously or into the muscles—and it is important to know which of these two localities is best suited for our purpose.

We know that subcutaneous inoculations give rise to high grades of immunity in horses and other animals when treated with snake venoms, tetanus, diphtheria and other toxins, much higher than if the same toxins were given intravenously. We also know that satisfactory results have been obtained after the subcutaneous administration of bacterial vaccines in man and animals.

Now the point at issue is, can anything be gained by substituting for the usual practice of subcutaneous inoculations that of intramuscular? With a view of gaining some definite information on this point the experiments detailed in this note were undertaken. Typhoid vaccine was selected as the type of a bacterial vaccine which produces a well-marked and easily measured immunising response in laboratory animals, such as rabbits or guinea-pigs. It is comparatively easy to follow up the changes which are to be found in the blood serum of these animals when treated with this vaccine. The vaccine used was prepared from a carefully selected strain of B. typhosus, and reliable for its immunising effects as demonstrated by numerous experiments in which the blood changes were investigated after its use both in man and animals. It was prepared from a broth culture grown at 37° C. for 48 hours, and sterilised by the addition of 0·5 per cent. carbolic acid. No heating was employed. Six healthy full-grown rabbits of the same breed and approximately of the same weight and age were selected. They were first of all tested to make sure that they were normal as regards agglutinins and opsonins for B. typhosus, and then divided into three lots of two each—viz., two for subcutaneous, two for intramuscular inoculations, and two

to act as controls. In those inoculated subcutaneously the inoculations were done on the front of the chest, and in those intramuscularly into the muscles of the thigh. All the inoculated animals received the same number of doses—viz., three each—and from the same brew of vaccine, first dose 100 millions, second dose 150 millions, and third dose 250 millions bacilli, with an interval of ten days between each dose. The blood to be tested was drawn off from the marginal vein of the ear into glass capsules, and put aside at room temperature for 24 hours until the serum had separated. The pooled sera of each inoculated lot was tested against the pooled sera of two control rabbits.

In carrying out the opsonic tests the serum was diluted 1 in 5 and then heated for 15 minutes at a temperature of 58° C. to destroy the complement and thermolabile opsonins. Two volumes of heated and diluted serum were added to two volumes of washed corpuscles and one volume of a suitable emulsion of 24 hours agar growth of B. typhosus, and after careful mixing filled into glass pipettes and incubated at 37° C. for 20 minutes. On being taken out of the incubator the contents of the pipettes were again mixed and films spread and stained in the usual way. From 50 to 100 polynuclear corpuscles were counted at each test.

On referring to the tables it will be seen that both sets of experiments give practically the same results. One might well infer from these results that there is nothing whatever to be gained by inoculating a typhoid vaccine into the muscles instead of subcutaneously, but on the contrary we should only cause the patient more pain and annoyance, for it is a well-known fact that intramuscular inoculations give rise to more pain than those given subcutaneously. Similar remarks would doubtless apply to the administration of other bacterial vaccines in common use.

It is worthy of note that the opsonic curves rise and fall fairly regularly with the agglutination curves. In both sets of experiments the first increase of agglutinins appeared on the third day and opsonins on the fourth day after the first inoculation; and also in both there were no indications of a negative phase on the day following the second and third inoculations or on the second day after the first inoculation. A negative phase if present at any time must have been of short duration. After the initial gradual rise in opsonins and agglutinins following the first inoculation, a well-marked fall made its appearance, which was again succeeded by another rise after the second inoculation. The second rise of opsonins was well marked on the day following the second inoculation, but a similar rise in the agglutinins did not take place until three days later, and was very well marked when it did take place, and remained steady at a high level until four days after the third and last inoculation, when the opsonins and agglutinins were at their highest level, and after this both showed a tendency to fall.

The tables given require no further explanations.

Conclusions.—1. The immunising response following the inoculation of typhoid vaccine in rabbits as measured by the presence of agglutinins and opsonins in the blood is the same whether the vaccine is given subcutaneously or intramuscularly. 2. In both methods of inoculation the agglutination and opsonic changes when plotted on a chart take somewhat similar courses, and in both an increase of agglutinins practically also means an increase of opsonins. 3. The intramuscular method of inoculating bacterial vaccines possesses no advantages whatever over the subcutaneous method, and as the latter gives rise to less pain and inconvenience it is to be preferred.

Kasauli, India.

LITERARY INTELLIGENCE.—Professor R. J. A. Berry, professor of anatomy in the University of Melbourne, is publishing an Atlas of Anatomy, for which a certain number of subscribers in advance are required as a guarantee to the publishers. In view of the importance of the work, and the reputation of the Anatomical School of the University of Melbourne, it has been thought desirable to make an immediate effort to secure the necessary guarantees, and to this end a very distinguished group of medical men and anatomists are assisting. The atlas will be published at the price of £2 2*s.* a copy, to be paid on delivery, and communications on the matter should be made to the honorary secretary, Dr. J. W. Barrett, 105, Collins-street, Melbourne, Australia.

THE UTILITY OF THE ANTILYTIC POWER OF HORSE SERUM.

BY FRANK C. EVE, M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO THE HULL ROYAL INFIRMARY.

DURING the last decade it has been shown abundantly that every cell in the body is capable of self-digestion by enzyme action. This may be a normal and useful process, as in the involution of the parturient uterus or in the resolution of a pneumonic lung; or it may be a morbid process, as in acute yellow atrophy, ulcer formation, and the like. Investigators have also proved that normal blood contains an anti-enzyme capable of inhibiting this process of autocytolysis.

But practical clinicians have been very slow to realise the immense practical importance of the applications of these facts, not only in the future but in the present. Perhaps the difficulty has been to cultivate the discerning eye which recognises a morbid process as essentially cytolytic in character, and also to cultivate some acquaintance with the vast and intricate subject of non-bacterial immunity which is almost essential to the intelligent and safe use of the antilytic power of normal serums, human and animal. Mr. E. C. Hort has demonstrated the healing effect of serum in gastric ulcer, and I have always found it effective in relieving pain in this condition. But one cannot see these ulcers, so I have selected two cases of intense superficial ulceration and one instance of severe hæmorrhagic purpura as my witnesses to the practical utility of the antilytic property of normal horse serum.

CASE 1.—The patient was a small boy, aged 6 years, who was successfully operated upon for congenital dislocation of the hip by the Lorenz method. For no apparent reason he subsequently became very thin, developing hæmaturia, ulcerated gums, and the most malignant ulceration of the arm I have ever seen. All these apparently autolytic manifestations were at once arrested by the local or internal administration of horse serum. Conceivably he was sensitised to the formation of these rictous cytolysins by the large hæmatoma and cell destruction inseparable from the bloodless operation. Dr. E. Barker tells me that the boy had always been thin, puny, and anæmic, which he ascribed to the advanced age of the father. A bone-setter wrestled with the patient's hip and produced an acute synovitis. On Nov. 24th, 1909, Dr. E. M. Hainworth did a successful Lorenz operation on the hip. All went well until the fourth day, when a smart hæmaturia appeared and lasted four days, and was followed by albuminuria for two and a half weeks. Next there was a small bedsore on the sacrum which soon healed. On Dec. 4th a small pustule formed on the back of the forearm, which was incised next day. An ulcer formed and grew to such an appalling size that by the end of seven weeks (when Dr. Hainworth called me in) it occupied three-quarters of the length of the forearm and more than one-half its circumference. In depth it was already dissolving the muscles and tendons. There was no slough, pus, or granulation, and the base and steep edges gave me the impression of cytolysis run riot. Accordingly, for four days the ulcer was dressed with gauze moistened with normal horse serum. As if by magic the inexorable course of the cell destruction was arrested, and granulations were visible at the end of the four days. In a few weeks the sore was covered by skin, but intractable adhesions and contractures have formed, as, indeed, was inevitable. Meantime there were four more attacks of hæmaturia, so that there was blood in the urine on the following dates: Feb. 24th and 25th; March 12th, 13th, 14th; 19th, 20th, 21st; 30th and 31st. Each of these attacks (except that on March 19th, which was insignificant) seemed to be arrested by a few doses (10 cubic centimetres) of serum by the mouth, but, of course, the evidence is imperfect. There was no subsequent albuminuria, as in the first attack. There were no casts, nor any evidence as to the point of origin of the blood, so that the serum treatment was directed against assumed endotheliolysins acting on the urinary blood-vessels, probably in the glomeruli. Finally, on April 23rd, a threatening condition of swelling, bleeding, and ulceration of the gums appeared. On the third day we applied horse serum to the gums every two hours. Without

other treatment the gums rapidly improved, and in ten days were noted as healthy. Under balcony treatment day and night, aided by two injections of T.R. (1/5000 milligramme), the boy has regained his flesh and general health. The plaster has been removed after the statutory six months.

CASE 2.—The patient was a well-nourished boy, aged 3 years, under the care of Dr. R. Grieve, to whom my thanks are due for this most instructive case. The patient was operated on for non-caseating tuberculous glands of the neck. On the eleventh day healing had apparently proceeded normally. On the fourteenth day the edges of the wound were reddened, and on the seventeenth day the wound was gaping. On the next day the temperature was 100° F., but it never exceeded this. By the twenty-fourth day the whole wound had become a deep, purulent, sloughing ulcer, which daily grew larger and deeper till there was fear that the great vessels might become involved. On the thirty-first day a dressing of gauze soaked in horse serum was applied (for four days). Further growth of the ulcer was at once arrested, and on the thirty-third day the first granulations were seen, after which healing proceeded rapidly. Assuming that no secondary infection occurred, the latent period of 13 days between the operation and the reddening of the wound does not suggest bacterial incubation but corresponds with an anaphylactic interval.

Latent periods such as these, which may be non-bacterial in origin, deserve careful collecting and collating to see if they agree with established latent periods such as the one to two weeks of the anaphylactic latent period after injection of horse serum into human beings. It may be noted that, on the views of Mr. Hort, this case may be explained without even mentioning the word bacterium. Thus one may imagine (1) the auto-inoculation of cytotoxins (by absorption of cells destroyed by the operation); (2) a refractory interval of accumulating antibodies (cytolysins); (3) after 13 days these have accumulated sufficiently to overpower the feeble new or injured cells in the wound, which are dissolved; (4) extension of ulcer by same process; and (5) arrest of cytolysis by applying antitryptic serum. I very much regret I had no opportunity of finding the antitryptic index at the time to see if the deficiency of antitrypsin was general or local.

CASE 3. *Purpura hæmorrhagica.*—The patient was a very healthy active old lady, aged 72 years, under the care of Mr. G. F. Briggs. On the first day of her illness she merely felt as if a cold was coming on, and she took two tablets of ammoniated quinine. On the second day large hæmorrhages appeared inside the cheeks and tongue. Then petechiæ, large and small, appeared all over the body, with loss of from a half to one pint of blood from the bowel. When I saw her an alarming stridor had commenced, presumably due to submucous hæmorrhage into the larynx. Acting on the assumption that circulating endotheliolysins were the cause of the trouble, 10 cubic centimetres of horse serum were at once injected, taking the precaution to inject over the ribs so as to be able to apply pressure if oozing proved troublesome, which, as a matter of fact, occurred. This was followed up by 10 cubic centimetres of serum by the mouth every four hours until 24 doses had been taken. The coagulation time was normal, but nevertheless we gave calcium chloride and lactate freely. Also we gave (alternately with the calcium) some acid. hydrochlor. dil. on account of its antagonistic action on the endotheliolysins of snake venom. No fresh hæmorrhages occurred after the serum injection and the patient rapidly emerged from the very critical condition in which we found her. Progress was uneventful and satisfactory. Blood platelets were absent on the third and eighth days, but were present in abundance after two months, and it is said that until these return the patient is in danger of relapse. The usual duration of this disease is supposed to range between two weeks and three months. If this be so, a large amount of credit seems to be due to the serum, but of course this is not conclusive.

General remarks.—Horse serum is undoubtedly a great addition to our armamentarium if used in properly selected cases and with proper precautions. Messrs. Allen and Hanburys supply it in three forms: (1) normal horse serum for oral or external use; (2) an aseptic form for subcutaneous injection; and (3) as antilysin, in which the antitryptic power has been somewhat enhanced by removing the globulin moiety of the serum proteids. These serums must be fresh and should be stored on ice.

How far is it necessary to guard against anaphylaxis? This, of course, is hypersensitiveness and a reversal or immunity; that is to say, if a second dose of certain poisons be given to an animal after an interval—e.g., ten days of more—the sensitiveness will be found to be enormously increased instead of the usual diminution. The phenomenon in human beings is at present seldom apparent, and the ill-effects of anaphylaxis seem to be trivial compared with its lethal manifestations in guinea-pigs. Still, from fear of the unknown, and out of respect to the idiosyncrasies of individual patients, it would be wise to take precautions: 1. By not administering serum subcutaneously or percutaneously for more than four days consecutively. 2. By not repeating doses after an interval of a few weeks or months. 3. If forced to do this, a massive dose is said to be safer than a small one. 4. By remembering that anaphylaxis is generally produced by the introduction of a small dose of antigen into a body already saturated with antibody. These hints must not be taken as authoritative, but will serve to indicate that this remedy is still in the experimental stage, and should not be used when older remedies will suffice.

Speaking provisionally, the use of these serums appears to be indicated whenever an undesirable form of cytolysis is proceeding unchecked in the hope that its powerful action in inhibiting cell digestion by trypsin or cell ferments may give us success when all other remedies are powerless. For instance, in the troublesome digestion of the skin which occurs round the edges of a gastric or intestinal fistula the local use of serum on gauze should be eminently successful. In noma, also, one would expect it to be beneficial, but I have had no opportunity of trying it in either of these conditions. Different samples of serum are said to vary in their "stimulin" action on dry and sluggish ulcers or sinuses. As this property cannot be measured in the laboratory (as can the antitryptic power) the only thing is to try another sample of serum if one is found to fail.

For my scanty knowledge of the new and important subject of the mechanism whereby "living cells are protected against non-bacterial toxins and enzymes—the products of their own and their neighbours' activity"—I am much indebted to Mr. Hort.[1]

Hull.

THE TREATMENT OF THE DYSPHAGIA OF LARYNGEAL TUBERCULOSIS BY ALCOHOL INJECTIONS INTO THE SUPERIOR LARYNGEAL NERVE.

BY J. DUNDAS GRANT, M.A., M.D., F.R.C.S.,

SENIOR SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL; SURGEON (THROAT AND EAR), BROMPTON HOSPITAL FOR CONSUMPTION, WEST-END HOSPITAL FOR NERVOUS DISEASES, ROYAL ACADEMY OF MUSIC, ETC.; PRESIDENT, SECTION OF LARYNGOLOGY, ROYAL SOCIETY OF MEDICINE.

AMONG the various remedies for the relief of the pain in swallowing, which has such disastrous effects in many cases of tuberculosis of the larynx, there is one which is deserving of careful attention. I refer to the injection of alcohol into the sensory nerve of the larynx, the superior laryngeal.

The local injection of alcohol for the relief of intractable neuralgia tic in the various branches of the fifth nerve is now a well-established means of treatment. It was originated by Schlösser of Munich, and Dr. Purves Stewart has submitted it to careful and extensive trial in tic douloureux with remarkably satisfactory results.

For the application of the method to the odynphagia of laryngeal tuberculosis we are indebted to Dr. Rudolf Hoffmann of Munich. Professor Denker of Erlangen recently recommended it to me on the strength of his favourable personal experience of its use in cases under his care. The results in the cases in which I have since then employed it seem to confirm his opinion. The duration of the relief is the striking feature of this method of treatment of the pain as such.

The solution that I use is the one recommended by Dr. Purves Stewart, consisting of 2 grains of hydrochloride of eucaine β in an ounce of 80 per cent. alcohol. The method of injection which I practise is the

[1] THE LANCET, Dec. 21st, 1907, &c.

one recommended by Dr. Hoffmann in the Proceedings of the German Laryngological Society for 1909, and he describes it so clearly that I cannot do better than reproduce his description in his own words. He "places the patient in a horizontal position and, with the thumb of the left hand, presses the sound side of the larynx towards the middle line so that the affected half projects distinctly; the other fingers of the hand lie on this. The index finger enters the space between the thyroid cartilage and the hyoid bone from without until the patient announces that a painful spot has been reached. With a little practice one arrives at it at the first go-off, when one has become familiar with the topographical relations. One now places the nail of the index finger on the skin (which has been previously disinfected) in such a way that the point of entrance for the needle lies opposite its middle. The needle is pushed in for about 1½ cm.; this distance is marked off on the needle perpendicular to the surface of the body. According to the thinness of the subcutaneous layer of fat, the perforation has to be more or less deep. The needle is then carefully moved so as to seek a spot at which the patient states that he feels pain in the ear. The syringe filled with 85 per cent. alcohol, warmed to a temperature of 45° C. (113° F.), is screwed on to the handle and the piston is then slowly pressed down. The patient now feels pain in the ear, the passing off of which he indicates by raising his hand. During the operation he has to avoid both swallowing and speaking; if, however, he makes a movement of swallowing we must follow the movement of the syringe with a light touch. The injection is kept up until no further pain occurs in the ear; then the needle is removed and collodion or sticking plaster is placed on the spot of injection without pressure."

The needle employed is one on Schlösser's pattern, its peculiarity being that the point is bevelled off much more obtusely than in an ordinary hypodermic syringe so as to avoid the risk of it puncturing a vessel. It has also to be fixed in a strong mount so as to overcome the resistance of the tissues. (*Vide* Figure.)

I append a short record of a number of cases in which I have recently tried this method of treatment.

CASE 1.—The patient, aged 30 years, had experienced pain in swallowing since January of the present year. Her pulmonary disease was of two years' duration. When seen in February she had extreme discomfort in the throat, especially during swallowing. There was infiltration with œdema of the epiglottis and both aryepiglottic folds to such an extent as to conceal the interior of the larynx. She then practised the inhalation of orthoform and anæsthesin which mitigated the pain in swallowing. In March galvano-caustic punctures were made, and these were followed by relief to her symptoms. A fortnight later she reported herself free from the choking feeling and the epiglottis was observed to have shrunk. In May I was called to her because for a week her pain had become much more intense; it shot up from the left side of the larynx to the ear and made swallowing almost impossible. I then injected a cubic centimetre of the eucaine and alcohol solution into the left superior laryngeal nerve. Two days later she informed me that the "awful soreness" was gone and that she could swallow without pain. The injection was followed by a burning pain which affected the teeth, but gradually died away, no trace of it remaining on the third day. She is at the present time still free from pain.

CASE 2.—The patient, aged 35 years, practically *in extremis*, had suffered intensely from sore-throat and pain in swallowing since February. He had infiltration of the epiglottis and both aryepiglottic folds on which superficial ulceration developed. He was somewhat relieved by the inhalation of local anæsthetic powders, and also by the galvano-caustic puncture, but for the week preceding the last inspection his pain in swallowing had become much more violent, being more marked upon the right side. As a last resource alcohol injection was administered on May 10th, and on the 25th he died as the result of complications connected with his pulmonary disease, but in the interval "was able to swallow his food better."

CASE 3.—A female patient, aged 22 years, when seen on May 24th, complained of such intense pain in swallowing as to prevent her from taking her food; during the preceding week she had not been able to take anything except thin liquids, the pain shooting up to the left ear. On inspection there was found infiltration of the left ventricular band with an irregular tuberculous outgrowth; there was infiltration of both vocal cords, with serrated thickening in the interarytenoid space; she had evidences of tubercle in both lungs. The injection of alcohol was administered, and on the same evening she was able to swallow custard. Since then she has been able to swallow ordinary food.

CASE 4.—A male patient, aged 30 years, complained of soreness of throat and extreme pain in swallowing; he had been unable to take anything more solid than egg-and-milk during the last three or four days. Examination of the larynx revealed infiltration of the epiglottis with superficial ulceration upon its laryngeal surface; both aryepiglottic folds were infiltrated; on the ventricular bands there were well-marked ulcers which extended to the vocal cords which were almost non-existent. Galvano-caustic puncture was made into the aryepiglottic folds. On June 7th the alcohol solution was injected and since then the patient has been able to swallow without pain; there is still (June 10th) a feeling of obstruction so that he is unable to take solid butcher's meat; this is probably to be explained by the presence of œdema of the right aryepiglottic fold; the œdema is possibly due to an inflammatory reaction following an imperfect penetration of the galvano-cautery point, the patient's throat being at the time unusually sensitive, and is likely to subside.

CASE 5.—The patient, aged 35 years, received an alcohol injection on June 7th on account of "tearing" pain most marked on the right side of the throat; this had been so severe that for a month he had been able to swallow nothing but liquids; there was also a general soreness of the throat. There were infiltration and ulceration of the epiglottis, a considerable portion of the right half being eaten away; both aryepiglottic folds and ventricular bands were infiltrated and superficially ulcerated. The vocal cords were comparatively unaffected. Three days later he was able to report that although there was still some general diffuse soreness, the "tearing pain" on the right side had gone and he was able to take some solid food. On touching the ulcerated surface with a probe it was unmistakeable that the right half of the larynx was more anæsthetic than the left.

CASE 6.—The patient, aged 21 years, complained of huskiness of the voice, which developed at the end of last February. She was seen on April 5th on account of pain, but there was then found very little extrinsic change. The ventricular bands were so infiltrated as to cover the whole of the right cord and part of the left one. She was then ordered an inhalation of a powder of di-iodoform. On the 30th, her pain being still considerable, a powder of anæsthesin and orthoform was substituted, and this gave considerable relief. I was called to see her on June 7th on account of increase in the pain during the preceding week; her swallowing, especially for saliva, was so severe that she described it as "cutting like knives." An injection of alcohol was then administered, and on the 11th she reported that her swallowing was easier the same night and that there was now no pain when swallowing, but only when coughing.

These cases were selected for this treatment on account of the extreme severity of the pain. They seem to me to confirm the favourable opinion formed of the method by continental observers and to justify its recommendation.

Cavendish-square, W.

THE NIGHTINGALE FUND.—This fund, which exists for the purpose of training nurses, has just issued its annual report for the year 1909. 42 nurses completed their training in the course of the year, 12 of whom have been retained in the service of St. Thomas's Hospital. Candidates are trained for various nursing services, including the Army Nursing Service. Applications should be made to the matron at Thomas's Hospital.

DOUBLE DERMOID CYST OF THE OVARIES WITH RUPTURE INTO THE PERITONEAL CAVITY.

BY REGINALD H. LUCY, M.B., C.M. EDIN., F.R.C.S. ENG.,
SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

A SINGLE woman, aged 32 years, was admitted to the South Devon and East Cornwall Hospital on Nov. 27th, 1909, for abdominal swelling, under the care of my colleague, Dr. E. L. Fox, who transferred her to my care. I found the patient to be a brunette, with a dull waxy complexion and an apathetic appearance. She complained of "a swelling of the bowels," and gave a history that when 11 years old she "had trouble with her water and was unable to pass any." At this time the "swelling" was first noticed, and also that the abdomen felt doughy and pitted on pressure. She commenced to menstruate at 15 years of age, and said the abdominal tumour had steadily increased ever since. She also described a very severe attack of pain "in the left side" about 19 months previously, followed by a rapid increase in girth of abdomen. Her legs have been swollen for the past five or six years, and she had occasionally vomited—otherwise she had been fairly healthy. There was no history of any special fall or abdominal injury; menstruation had been regular, micturition at times difficult, and bowels generally constipated. Temperature, pulse, and urine were normal.

On examination the abdomen was found to be uniformly distended; the skin was tense and pale, but on placing the hand anywhere on its surface a hollow was left which remained for some considerable time. No free fluid could be detected and examination seemed painless. It was at first thought possible that these physical signs were due to fæcal accumulation, but the administration of castor oil for several days caused no diminution of the tumour. Moreover, on examining the rectum several hard masses, which did not pit on pressure, but were certainly tender, could be felt in Douglas's pouch.

A diagnosis of dermoid cyst of the ovary was made, and on Dec. 8th, 1909, cœliotomy was performed, after painting the skin with equal parts of liq. iodi fort. and spt. ætheris during the induction of anæsthesia. On incising the parietes in the mid-line below the umbilicus the deeper layers were found to be opaque and thickened; on careful dissection primrose-yellow material, closely resembling "lanoline," escaped and proved to be filling the general peritoneal cavity. My assistant, Mr. C. E. Russel Rendle, emptied the abdominal cavity by scooping out handfuls until a large washhand basin was filled to overflowing with this tenacious, greasy, odourless material. Eleven pounds by weight were thus removed. A cyst was then found at the back of the abdomen, pale pink, with veins running along it vertically, and a definite orifice at the upper pole from which similar material exuded. A broad band resembling bowel was found springing from the upper end of the cyst and connected by curious worm-like adhesions to the parietal peritoneum. On breaking these down the band proved to be the remains of the great omentum. This was divided after ligature. The cyst was now lifted out of the abdomen and it was found to be firmly attached to the right cornu of the uterus; this pedicle was clamped, transfixed, and tied off with iodine catgut. The left side of the pelvis was seen to be occupied by an opaque oval swelling, with an area of the size of a shilling about its centre occupied by a tuft of dark hair. This tumour was enucleated, found to be attached to the left cornu of the uterus, tied off and removed. The abdominal viscera were now seen to be packed away against the vertebral column in the upper part of the abdominal cavity; the intestines were much collapsed, pinkish-grey in colour, and their serous coats were dull, opaque, finely granular, and covered with processes resembling wet string, though the several coils were not matted together. The great omentum (beyond the thick grey band previously referred to) was not recognisable and the liver and spleen were pushed out of sight. The whole of the parietal peritoneum was coated with a layer of sebum, making it opaque anteriorly but more translucent when traced towards the spine. On the left side behind the upper compartment of that rectus muscle the peritoneum showed a patch, some 2½ inches in diameter, covered with black hair; this was dissected away and the raw surface covered by a peritoneal graft. The broad ligaments having been fully opened up by the enucleation of the tumours a purse-string suture of catgut was run round the edges of each broad ligament and tightened over stout drain-tubes of large diameter passed down to the bottom of each pouch and their upper ends brought through the centre of the parietal incision. A third tube was led from the pelvic brim and through the right kidney pouch by a loin puncture. Any toilet of the peritoneum beyond wiping out with gauze as much of the sebaceous material as could be seen between the viscera was futile and apparently unnecessary. The peritoneum had shown so easy a tolerance for so long a time—presumably at least 17 years—that it was deemed capable of taking care of what foreign matter still remained. The parietes were closed in mass by silkworm-gut sutures, several provisional ones being placed where the two drain-tubes emerged. Continuous rectal instillation of warm saline solution was established on return to bed. The temperature rose to 101·8° F. and the pulse to 112 the evening after operation; reached 101·8° and 120 respectively on the second evening; and declined to 98° and 92 on the sixth day, when all drains were removed. The temperature rose again to 101° on the evening of the eighth day, but descended to normal on the thirteenth day, with a third elevation to 99·6° on the evening of the nineteenth day, lasting till the twenty-third day. These rises of temperature were usually accompanied by a free discharge of serum, containing flakes of sebum, along the track of the drain-tubes, so that the provisional sutures were not tightened till the sixth day, and all were removed on the eleventh day. The patient got up on the twenty-fifth day and went to the Pearn Convalescent Home on Feb. 2nd. Metrostaxis did not follow the operation and menstruation has not occurred since.

It is difficult from the woman's history to fix the date when first the peritoneal cavity became invaded by the dermoid material, though it is probable that the tumour of the left side "leaked," so to speak, some 19 months previously to her admission into hospital. She is quite positive that the pitting of the abdomen has existed at least from puberty, so one is constrained to believe the process to be one of long duration. Fortunately for her the invasion was slow and leading a quiet life she was not subject to the liability to accidental injury common in those leading a more active outdoor life. Also there was no evidence of any infection in the sense of a bacterial invasion of the abdominal contents.

This case presents a most remarkable instance of the tolerance shown by a serous membrane of large superficial area and complex distribution to the presence of material foreign to its usual secretion. The bowels were generally constipated but not more so than in a woman of sedentary occupation and placid mind. Up to the time of operation her menstrual functions had been regularly performed from puberty, though the discharge had latterly become paler. No sign of ovarian tissue was discoverable other than the dermoid tumours.

I am indebted to our honorary pathologist, Dr. W. L. Pethybridge, for the following report:—

> The membrane lining the larger cyst was of the usual type and contained a few teeth (not attached to bone) and numerous masses of dark-coloured hair, the hairs varying in length from an inch up to 10 or 12 inches. The small cyst was about the size of the fœtal head and also contained hairs and teeth. I did not find anything that looked like ovarian tissue, although I believe the patient menstruated. The two masses together weighed 8½ lb. and the material previously removed 11 lb.

Instances of dermoid cysts suppurating and bursting into the peritoneal cavity, generally with fatal results, are not uncommon. Records of dermoids of the ovary becoming attached to the parietal or visceral peritoneum and discharging their contents through the skin, bladder, rectum, or vagina are numerous, but I cannot find in the literature at my disposal a case analogous to that just narrated.

The question arises whether this case of mine should be classed amongst those which Bland-Sutton[1] designates as instances of "epithelial infection," of which he mentions four (Moore, Kolaczek, Fraenkel, and Crowitz), or as "malignant embryomata." The slow progress of the disease, the large quantity of pultaceous material found free

[1] J. Bland-Sutton: Tumours, Innocent and Malignant, fourth edition, pp. 496-97.

in the peritoneal cavity without any evidence of active peritonitis, and the absence of any visceral metastases seem to preclude the latter classification, though there were two undoubted "secondary nodules" in "the form of grafts" and "confined to the peritoneum." Time alone will show to which category my case belongs.

Ed. Melchior[2] gives one personal observation and four analogous cases previously published of peritoneal pseudo-metastases of ovarian dermoids. His patient was a woman, aged 48 years, with dermoid nodules on the parietal peritoneum, the small intestines, gastric serosa, and on the diaphragm.

SURGICAL SECTION.

Discussion on Syphilis.

A DISCUSSION on Syphilis, introduced by Mr. J. ERNEST LANE, was held at the two meetings of this section on June 7th and 14th, Mr. RICKMAN J. GODLEE being in the chair.

Mr. LANE said that as far as their present knowledge was concerned syphilis was a malady which could only be mitigated, and which did not seem likely ever to be exterminated. The disease seldom now produced the terrible mutilations with which they were familiar in the past; still, its remote effects, its influence on the nervous system and on many medical and surgical conditions could not be ignored. It was a matter of the utmost difficulty to gauge the incidence of a disease such as syphilis, and a glance at hospital records might give the impression that it was on the increase; for example, the attendances of out-patients at the London Lock Hospital was 34,649 in 1908, whereas ten years previously the number was 25,314, a difference of over 9000 attendances. Those figures, of course, only applied to venereal diseases in general and not to syphilis in particular, but the ratio of syphilis to other venereal diseases appeared to remain fairly constant. That increase in the number of cases treated did not necessarily mean an increase in the amount of syphilis, but might be ascribed to the fact that the public nowadays more fully recognised its gravity and the necessity for prolonged treatment. More reliance might be placed on the returns issued by the Army Medical Department, which showed a steady decrease in the amount of venereal disease in the army in the course of the last quarter of a century. Taking it for granted that the extent of syphilis was considerably less than formerly, and that it was of a less virulent type, one was led to inquire into the causes for that diminution, both in its amount and in its gravity, and the conclusion that would probably be arrived at was that it was due partly to a more efficient system of treatment, partly to the better recognition by the general public of the laws of hygiene, of the dangers of the disease, and of the disasters that might occur if treatment was neglected, and partly due to the process of natural immunity which after the lapse of years must show its influence on any disease. One of the best measures of prophylaxis against syphilis was efficient treatment. At the present time a mistake in diagnosis should be impossible, owing to the momentous discovery of the spirochæta pallida by Schaudinn in 1905, and by the subsequent investigations by Wassermann on the serum diagnosis of syphilis. If the chancre existed, the presence or absence of the spirochæta would prove its nature, while if the sore had healed, then the Wassermann test would clear up any doubts. He (Mr. Lane) had seen a sore of only one day's duration, or possibly recognition, in a patient who had exposed himself to contagion, and who had been keeping a keen look-out for possible contingencies; that sore was of the minutest dimensions, and might have been a simple abrasion, might have been a commencing chancroid, or might have been herpetic in nature, but on microscopical examination the spirochætæ were found in large numbers in the exudation from the sore, and consequently he was enabled to place that patient on antisyphilitic treatment almost immediately after the appearance of the initial lesion. Personally Mr. Lane preferred not to limit himself to any one particular method of treatment, and did not consider that one routine plan was applicable to every case of syphilis, but he would prefer to treat every case on its merits and according to individual peculiarities. Fortunately, in the majority of cases, syphilis was a benign disease, and one which was particularly amenable to treatment, and in a simple case there was no necessity to look beyond the time-honoured method of administration of mercury by the mouth in the form of pills or mixture, and most cases conld be conducted to a satisfactory conclusion by that, the most simple and most convenient of plans. But it was not every case of syphilis that would yield to such simple measures, and it was not every patient who was tolerant of mercurial pills or mixtures. Intramuscular injections might be given in the form of the insoluble or the soluble preparations of mercury, and of the two the insoluble salts were undoubtedly the more valuable, for they produced results which were surprisingly constant in the rapidity with which they brought under control manifestations which had previously resisted other kinds of treatment, and in controlling the subsequent course of the disease. The two reliable preparations of the insoluble salts were, first, calomel, and secondly, mercury suspended in some fatty basis, and usually designated grey oil, though occasionally christened by the name of someone who had devised some modification of the compound originally introduced by Lang of Vienna. Of those two methods, that of calomel injections was far the more efficient. A course of 12 injections given once a week was usually sufficient to clear up any urgent symptoms, and to check the progress of any rapidly destructive lesion. The other insoluble mercurial preparation which had achieved much popularity was grey oil, consisting of mercury very finely subdivided and combined with some fatty basis. Its action resembled that of calomel, but it was not nearly so powerful and fell far short of it in efficiency, though it had some compensatory advantage in that the resulting pain was much less severe. Whilst calomel might be employed in the intractable cases, in those in which some serious complications were present, grey oil was more suitable as a routine treatment, and for that reason was more in vogue in military and naval hospitals, where the patients could be kept under constant observation and supervision. In regard to the treatment by injection of soluble mercurial preparations its drawbacks were obvious and its advantages were visionary, and the method compared unfavourably with all the other means by which mercury might be introduced into the system. The principal objections to the inunction treatment were that the patient was compelled to regulate his habits according to the requirements of the treatment, and had to follow out a *régime*. There was also great uncertainty as to the amount of the drug which would be absorbed, and in some cases its action appeared to be absolutely inert. The general impression in this country appeared to be that mercurial treatment prolonged for two years was sufficient to guarantee, if not a cure, a subsequent immunity from symptoms. Such a supposition was, in his opinion, fallacious and dangerous, as was evidenced by the large number of cases of late syphilis, specially involving the higher nerve centres, with which anyone who was in the habit of treating the disease must be painfully familiar. He had for a long time past recommended that treatment should be prolonged over a minimum period of five years, and in the case of those who were of a neurotic disposition, and whose business entailed a strenuous and anxious life, he advocated that it should be extended over seven years. Obviously the treatment could not be continued for all that length of time, but should consist of one initial course, extending if possible over a year, then an intermission of three or four months, and then a series of shorter courses of treatment and more lengthy periods of intermission until the expiration of the number of years deemed necessary for each individual case. Long before the expiration of that time the patient would in most instances have been incapable of transmitting the disease to his wife or to his offspring, but though he might have attained that point, he was not himself necessarily immune from the occurrence of nerve or visceral syphilis. They were not yet sufficiently conversant with the exact significance of the Wassermann test for syphilis; no doubt the test often remained positive long after the patient had

[2] Ed. Melchior: Berliner Klinische Wochenschrift, 1908, p. 34.

ceased to be a source of danger to others, but if positive it appeared to him to be a sufficient indication that the patient would be benefited by further courses of treatment until the test became permanently negative. The iodides were of the greatest value in getting rid of certain syphilitic manifestations, though they did not appear to be capable of eliminating the poison of syphilis in the slightest degree. He had seen cases in which the administration of iodipin was productive of excellent results; but, on the other hand, he had seen a patient who suffered from almost complete atrophy of the gluteal muscles in consequence, and another who was leaking out iodipin from many punctures in his buttocks, to his great embarrassment and disgust, and possibly to that of others. For many years past arsenic had been recognised as a valuable adjunct to mercurial treatment, especially in the form of Donovan's solution, a preparation which was specially indicated in the treatment of late and intractable syphilides. But the amount of arsenic that could be introduced into the system by way of the stomach was very limited, the dose being from 1/60 grain to 1/15 grain, and any larger doses were liable to be followed by signs of arsenical poisoning. In order to facilitate the introduction of larger quantities of arsenic into the system, certain compounds known as the arylarsonates had of late years been introduced and had met with some amount of success and support in the treatment of syphilis. The success obtained by this treatment was at first most encouraging, and certainly it caused the disappearance of the early symptoms of the disease with wonderful rapidity. In very few of the cases were symptoms of arsenical intolerance observed, and those disappeared on prolonging the interval between each injection. But eventually he met with a catastrophe so grave and so disturbing that since that event he had entirely discarded that form of treatment. A patient, aged 49 years, an old soldier, was admitted to the Lock Hospital suffering from a typical indurated sore and a papular syphilide on the face and trunk. He was given nine injections; on the day after the seventh injection he noticed general fogginess of vision in both eyes, which gradually increased, but he omitted to mention this fact until the day after the ninth injection. Then on examination there were found to be tremor of both eyes and difficulty in counting fingers held up at a distance of 12 inches in a strong light. On ophthalmoscopic examination both discs were found to be pale and indistinct in outline, with the vessels of normal calibre. A very careful general examination showed absence of any signs of arterial degeneration, the kidneys were apparently perfectly sound, and the physique and general health were perfectly good. He was treated with large doses of strychnine hypodermically and subsequently with calomel injections. Examination of the eyes four months later showed a perception of hand-movements at a distance of 4 feet, equal in both eyes; both discs were markedly atrophic, the atrophy not indicative of a previous neuritis, whilst there were well-marked pigmentary changes at both maculæ suggestive of inflammatory or degenerative changes. Shortly afterwards he (Mr. Lane) met with another very similar case of a patient who had been treated by a private practitioner. He felt it his duty to draw the attention of the profession to the danger which might ensue from the employment of those preparations. In confirmation of his warning the treatment had been discontinued by such authorities as Professor Neisser and Professor Finger, owing to the occurrence of similar mishaps. It could not be denied that the results of this treatment had been satisfactory in some of their military hospitals, but opinions as to the value of the arylarsonates differed widely amongst the officers of the Royal Army Medical Corps. Whereas some regarded them as a prophylactic against any further developments of the disease, a contrary opinion was expressed by a memorandum issued in January of this year by the expert committee on venereal disease in the army to this effect: "That the utility of these preparations as a prophylactic against syphilis has not been proved, and the committee does not recommend their administration for that purpose." It seemed that the arylarsonates did in a certain number of cases considerably modify the evolution of the early symptoms of syphilis, but they were just as liable to be followed by relapses as was the treatment by mercury, which also appeared to be more reliable; that they had in the various methods of administration of mercury a perfectly satisfactory remedy for the treatment of the disease, and one which, with ordinary care, was at any rate free from danger. In the presence of a disease such as syphilis, which in the vast majority of cases was amenable to mercurial treatment, the effects of which, though slow in many cases, were for the most part sure and safe, he could not think they were justified in having recourse to remedies such as those arsenical preparations which were capable of causing blindness. But with a disease such as trypanosomiasis, which was almost certainly fatal unless drastic measures were resorted to, the employment of these remedies was not only justified but was imperatively called for, since the possibility of blindness was better than the certainty of death.

Mr. A. FLEMING spoke on the way in which laboratory work could aid in treatment. The laboratory diagnosis of syphilis could be divided into two parts—finding the organism, the spirochæta pallida, and performing the serum test, Wassermann's reaction. The organism could rarely be discovered except in the primary and in some secondary lesions, as in the other cases either the lesions were in parts of the body that were not accessible, or the organisms were so few and far between that they could not readily be found. The methods which had been used to demonstrate them were these: staining methods, cutting sections of a piece of material removed by operation after impregnation with silver, dark-ground condenser, Chinese ink (Burri's method). The first two he would say no more about, as they had been almost entirely replaced by the other methods. The dark-ground condenser had come largely into use for this purpose in the last year or so. By this means they were able to see the spirochætæ as very definite clear spirals on an absolutely dark ground. This method also had the advantage over all the other methods, that one was able to see the characteristic movements of the organisms. The disadvantage of the method was the necessity of obtaining a special condenser and of fitting it into one's microscope each time one wanted to look for the spirochætæ. A much easier method, and one which required no elaborate materials and very little skill, was Burri's Chinese ink method. Here all one had to do was to put a small drop of Chinese ink on a slide, mix with it some serum squeezed from a chancre, and spread the whole on a slide in a thin film. The film was allowed to dry and was examined directly under the microscope. He had found that this method enabled him to trace the spirochæta with as much certainty as, and with much less trouble than, by the use of the dark-ground condenser. The disadvantage was that it did not reveal the movements of the spirochæta. The second test for syphilis was the serum reaction. While the spirochætæ were most readily found in the primary stage, it was in this stage that the serum reaction was of the least value, although even here it gave positive reactions in between 60 and 70 per cent. of cases. In the secondary stage, where lesions were present, one obtained a positive reaction in almost every case, and the same might be said of the tertiary stage where there were any active lesions. Out of about 100 cases of secondary syphilis he had only found one, or possibly two, cases where he did not obtain a definite positive reaction. In congenital cases also he had found that out of about 40 cases he had only obtained one negative result where the clinical diagnosis seemed quite definite. In parasyphilitic cases there was a very marked difference between general paralysis and tabes in respect of the serum reaction, for whereas in general paralysis one obtains a positive reaction in every case, in tabes it was in only about 65 to 70 per cent. that that reaction was shown. In making his observations on the serum reaction he had used not Wassermann's method but a method which was in principle the same as that of Hecht although the technique was different.[1] The greatest objection which had been urged (mainly on theoretical grounds) was that by this method one would obtain a positive result in some cases which were not syphilitic. If that were so then it would render the method almost valueless, but he strongly maintained that this objection was absolutely devoid of foundation. He had now tested over 500 individuals who were supposed to be free from syphilis. Some of those were patients attending the hospital for diseases other than syphilis. Of those 500 cases only some 12 gave positive reactions, and on going into

[1] THE LANCET, May 29th, 1909, p. 1512

the history of all of those facts were elicited which made it very probable that in all there had been a syphilitic infection. In no other disease with the exception of leprosy and trypanosomiasis had he found a positive reaction. He thought it was likely that the observers who found positive results in normal people were either using a faulty antigen or were using it too strong, as, of course, by using too strong an antigen, one could easily make all of them give a positive reaction. Last July, at the British Medical Association meeting at Belfast, Fleet-Surgeon Bassett-Smith made some objections to the method he (Mr. Fleming) had used, but later, in the *British Medical Journal*, he (Fleet-Surgeon Bassett-Smith) stated that as the result of further experience his objections had been unfounded, and that by this method he had obtained in some cases a positive result earlier in the disease than he had obtained by the original Wassermann method. Recent figures comparing the two methods were those of Hecht in the *Zeitschrift für Immunitätsforschung* last month. From those it would be seen that not only was the simpler reaction absolutely specific but that it was a more delicate reaction. But apart from any question of greater accuracy of the modification he had used there could be no question as to its greater practicability. All one required was some extract of heart, some serum (the amount which could be obtained in an ordinary blood-capsule), and some sheep's corpuscles, which could be obtained from the butcher, whereas in Wassermann's method one required in addition some serum of a rabbit which had been immunised to sheep's corpuscles and some fresh guinea-pig's serum—serious drawbacks if one did not possess a vivisection licence. The place of the rabbit and the guinea-pig were taken by the hæmolytic substances which were present naturally in human serum, and in the few cases where this hæmolytic power was deficient (about 5 per cent.) it could be supplied by the addition of a little fresh serum from a normal individual. Mr. McDonagh, in a recent paper in THE LANCET,[2] emphasises the fact that one of the great reasons why Wassermann's reaction did not succeed in all cases of florid secondary syphilis was that in heating the serum previous to the test (as was necessary in Wassermann's method) the complement of the serum was converted into complement which possessed the combining properties but not the active properties of complement. If that was so, then it put Wassermann's method at a very great disadvantage to Hecht's, in which the serum was not heated. Possibly the greatest use of the serum reaction would be to control treatment. There seemed no doubt that energetic treatment with mercury would destroy the reaction. If treatment were stopped too early the reaction would return after an interval of a few months, but if treatment had been energetic enough, or if it had been sufficiently prolonged, then in the majority of cases the reaction seemed to have disappeared for good. It appeared to him that the most effective treatment was by injection of grey oil, as with this form of treatment a fair number—about 30 per cent.—lost their reaction after only nine months' treatment. He had, however, not tested any cases treated for more than 12 months in this way, and possibly, although the reaction seemed in some cases to disappear fairly early, yet in the long run no greater percentage would lose it than with other forms of treatment. After grey oil injections, inunction of mercury seemed to have the most effect. Treatment by means of pills of hydrargyrum cum cretâ appeared to be the least effective of the methods he had made observations on, as even after three years' treatment in this way more than half of the cases tested still gave positive results. After the surgeon had treated the case for a reasonable time, he should stop treatment for a month or two, and then have the serum test done. If this was positive, then treatment should be continued; if negative, the test should be repeated after an interval of six months or a year, and if the patient wanted to be further reassured, the test should be repeated at later intervals.

Major H. C. FRENCH, R.A.M.C., communicated a paper in which he wrote that to treat syphilis adequately, and so keep the disease under effectual control, it appeared to be absolutely essential to recognise it in the earlier and more remediable stages. If the spirochæta pallida was demonstrated, or if the classical sign of induration existed in the chancre and in the adjacent lymphatic glands, they should, he considered, vigorously attack the disease by judicious mercurial treatment. The Wassermann serum test could not be implicitly relied on in the primary stage. He did not agree with those persons who counselled a waiting policy in all cases until the rash was present. The rash, in his experience, did not as a rule appear until from 14 to 16 weeks from the date of exposure to contagion. Delay for that period in commencing treatment was unjustifiable in probably 90 per cent. of cases, and markedly aggravated the disease. In a small minority, however, where induration of the chancre and discreetly enlarged lymphatic glands were not marked, they must perforce wait for more definite evidence, such as rash, &c. A course of mercurial treatment before the date of onset of rash was, he considered, worth two courses later as regards the ultimate beneficial effect on the disease, as well as in its effect in guarding against parasyphilitic affections. As regards duration of treatment, a period of two years with intervals between courses was his usual rule—where inunctions or hydrargyrum cum cretâ with opium had been used; but when insoluble preparations of mercury, such as grey oil, were employed, a third year's course of treatment was often necessary to dissipate the remaining external evidences. Inunction of unguentum hydrargyri was now receiving much more attention in the British army. He employed it in the majority of cases in doses of two-thirds to one drachm, with a daily hot bath (preferably sulphur), and 30 to 50 rubbings formed a course in early syphilis, according to the indications of the particular case and controlled by the weekly weight. The Wassermann serum diagnosis test was by no means always conclusive before the development of the constitutional signs of rash and generalised glandular enlargement. The Wassermann test gave valuable results in parasyphilitic cases. Iodide of potassium was a valuable drug in treating certain phases of syphilis, and its utility was more obvious the longer the period from the primary evidence of the disease. He did not think it should be used to the exclusion of mercury, but to supplement it.

Mr. J. E. R. MCDONAGH said that a new drug called Ehrlich-Hata's preparation, No. 606, which was dichlorhydrate-dioxy-diamido-arsenobenzol, had just appeared,[3] which was said to work a most wonderful change in syphilitic lesions at any stage of the disease after one injection of 5 grains. Hata had already used it in Frankfort in more than 100 cases of syphilis without meeting with any untoward symptoms. Out of 25 patients reacting positively 23 gave a negative Wassermann after one injection.

Mr. C. F. MARSHALL said that the treatment of syphilis was drifting too much into the hands of experimental chemists. They were asked to abandon the simpler preparations which had stood the test of time in favour of new-fangled and complicated preparations too often of instable composition. One new preparation was followed by another with such frequency that it was impossible to test their value. With regard to injections, he thought the method of injection more suited to acute than chronic conditions—i.e., to conditions where rapid action was required. However, he preferred inunction in such cases. Injections no doubt were useful in the case of the army and navy, but were irksome and too expensive in private. With regard to arylarsonates, he considered them not only unnecessary but absolutely contraindicated on account of the possibility of blindness. Many cases were reported, and many others were not reported. Syphilis was quite bad enough without adding blindness to it. Potassium iodide was useful in all stages of syphilis. With regard to the results of excision of chancre the evidence was contradictory. The earliest possible excision often failed.

Dr. GEORGE PERNET pointed out that on clinical grounds alone the pill method of treating syphilis had not proved satisfactory; that was being confirmed by the Wassermann test in the laboratory. Whilst admitting that inunctions were valuable, he contended that the best method of dealing with the disease was that of intramuscular injections, not in a routine manner, but in properly selected cases. In private practice he had found it efficient. Calomel was the sovereign sheet-anchor in serious complications of syphilis, such as optic neuritis, threatening cerebral mischief, and in obstinate tongue lesions and palmar syphilides, for instance. These injections were at times painful, but not always. Dr. Pernet had found that calomel, 40 centigrammes to the cubic centimetre, in 5- and 10-centigramme doses, was sometimes well borne *quâ* pain. But Zambeletti's preparation

[2] THE LANCET, April 2nd, 1910, p. 922.

[3] THE LANCET, June 18th, 1910, p. 1719.

was usually practically painless and more reliable from that point of view. As to grey oil, that was a most valuable preparation, less potent than calomel, but very suitable for the usual run of cases. He employed French preparations of the strength of 40 centigrammes to the cubic centimetre, as for calomel. With a specially graduated syringe these preparations were not likely to lead to errors in the dose. The insoluble preparations had their drawbacks, but so had all methods of treatment. In a paper read last year before the American Medical Association in Atlantic City Dr. Pernet had gone into this question, as also into the question of the technique, so there was no necessity to go into details.[4] Soluble preparations of mercury were also valuable, but they had to be given much more frequently, in some instances daily, as in the case of the benzoate of mercury; but they were often useful to start a treatment and test a patient. All recent experience had demonstrated that mercury was the basis of treatment, for atoxyl and derivatives had failed. Dr. Pernet concluded by stating that syphilis should be treated for at least four years, vigorously during the first two, then less so for another two. After that the patient should have further courses of mercurial treatment at intervals.

Mr. HUGH WANSEY BAYLY said that by the help of the reflecting immersion condenser, commonly called the "ultra-microscope," the treponema pallidum could be easily detected in scrapings from the site of the inoculation even before any definite chancre had developed. Much valuable time was thus gained and the patient was saved the discomfort of the secondary manifestations. He could not agree with Mr. Fleming's opinion in regard to the value of the Chinese ink method, as it was frequently very difficult to differentiate the various spirochætæ by this method and the diagnostic value of the movements was lost. Neisser had shown by means of the Wassermann reaction that the earlier anti-syphilitic treatment was commenced the more probability there was that early and permanent cure would result, and therefore the "ultra-microscope," which in the absence of local antiseptics settled at once whether the commencing pimple or ulcer was the site of a syphilitic inoculation or not, must be considered of the greatest possible value, both from the point of view of surgeon or patient. Calomel injection seemed much better than pill treatment, but not so good as inunction as estimated by the Wassermann reaction. Potassium iodide and the arylarsonates had no effect on the Wassermann reaction as far as three months' treatment was concerned. He had tried Mr. Fleming's technique and had come to the conclusion that in the long run Mr. Fleming's technique did not save time or trouble and was not so reliable as Wassermann's original technique as modified by him (Mr. Bayly).[5]

Mr. JONATHAN HUTCHINSON said that he was in favour of continuous treatment of syphilis. At Aix, after patients had gone through a course, they were told to come again in six months' time for another course. He had seen the failure of this system to prevent bad symptoms occurring. The clinical results of keeping patients under mercury by the mouth for two years with due precautions as to abstention from alcohol were that nine out of ten remained free from symptoms as long as they could be followed up; they married and had healthy children. He had brought forward a series of cases in which patients had been treated by oral administration and within a certain number of years had contracted primary chancres and had syphilis all over again.

Captain L. W. HARRISON, R.A.M.C., said that it would be impossible to carry out the treatment of syphilis by inunction in the army.

After Mr. LANE had replied the proceedings terminated.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on June 3rd, Dr. J. DUNDAS GRANT, the President, being in the chair.

Mr. SOMERVILLE HASTINGS showed a case of Laryngeal Paralysis following Partial Removal of the Thyroid Gland. A woman, aged 41 years, had suffered from goitre for 15 years. The whole gland was extensively involved, but the left side more than the right. On May 2nd, 1910, the greater part of the tumour was removed piecemeal by resection-enucleation. In doing this the right superior and left inferior thyroid arteries were divided. Loss of voice and slight dyspnœa were noticed immediately after the operation, but owing to an attack of broncho-pneumonia the examination of the larynx was deferred to May 24th. The patient was unable to cough; she spoke with much waste of air in a feeble voice. There was some expiratory stridor. The cords were pale; they were held immovable in incomplete adduction, and flapped forward in expiration.

The PRESIDENT showed cases illustrating the Treatment of the Dysphagia of Tuberculosis of the Larynx by injection of alcohol into the superior laryngeal nerve. (A paper on this subject by Dr. Dundas Grant is published on p. 1754 of this issue.)

Dr. W. JOBSON HORNE showed specimens and a case illustrating Diseases of the Ventricle of the Larynx. 1. A series of microscopic sections cut vertically through the entire length of one side of the soft parts of the larynx, illustrating the development of an innocent neoplasm, dependent from the roof and tending to present itself at the mouth of the ventricle. This specimen was accidentally met with whilst investigating a series of larynges obtained in the Pathological Institute of Berlin by Professor Virchow. 2. A section of the right half of the larynx, showing true prolapse of the mucous membrane lining the ventricle. The detachment of the membrane had been brought about by ulceration and destruction of the cartilage secondary to a gumma. 3. A woman, aged 48 years, who had suffered from hoarseness for many years. The larynx presented swelling and distension of the right ventricular band, and when first examined the appearance suggested a projecting body from the right ventricle obscuring a view of the vocal cord in its entire length; both cords moved equally.

Dr. DAN MCKENZIE showed a case of Bilateral Abductor Paralysis from Central Nerve Disease in a male, aged 56 years. The larynx presented the picture of bilateral abductor paralysis with incipient paralysis of the internal tensors. The cords were approximated when at rest, but they did not come fully into contact during attempts at phonation. The patient had frequently suffered from dyspnœa during the last two years, and had had several attacks of acute glottic spasms; he had steadfastly refused to submit to tracheotomy. There was also at times some difficulty in swallowing liquids, the mobility of the tongue was impaired, and articulation was affected to some extent. The pupils were unequal and responded little, or not at all, to light. The knee-jerks were active and there was no Rombergism. The symptoms therefore pointed to a lesion in the bulb.

Dr. ANDREW WYLIE showed a case of Obstruction of both Nostrils in a girl, aged 11 years; she was said to have had the obstruction all her life. No operation was ever performed upon the nose. Marks of hereditary specific disease were seen; the Hutchinson teeth were characteristic. The hearing was normal. The septum was thickened and the anterior ends of both inferior turbinals were firmly adherent to it, except at the lower border on the left side, where a fine probe could be passed. The obstruction was chiefly anterior, as posterior rhinoscopy showed a normal condition.

Dr. H. W. FITZGERALD POWELL showed a rapidly growing Tumour filling the right side of the post-nasal space, pushing the soft palate before it. The patient was a male, aged 42 years. The hard and somewhat elastic swelling affected the right side of the palate and right tonsil, causing difficulty of breathing and obstructing the right nasal chamber. Iodide of potassium was given, though there was no specific history, and exploratory puncture yielded no fluid. Microscopic section was said to resemble in appearance the condition found in sarcoma.

Dr. WALTER G. HOWARTH showed a case of Tuberculosis of the larynx with considerable Dysphagia treated and relieved by venous congestion. The patient came on account of dysphagia, great swelling of the epiglottis and arytenoids, obscuring the larynx from view. For three weeks he had been wearing a fairly tight elastic band round the root of the neck for 22 hours out of 24. The band was fitted with a pad which lay in the hollow between the cricoid and the top of the sternum. The band could be tightened by a buckle at the back of the neck. Swelling was so far diminished that an easy view of the larynx was obtained, and there was much greater facility for swallowing.

[4] Pernet: The Intramuscular Treatment of Syphilis, with Special Reference to the Insoluble Preparations of Mercury. A Critical Review. THE LANCET, July 24th, 1909.

[5] THE LANCET, May 29th, 1909, p. 1523.

Dr. JAMES DONELAN showed a case of Tuberculous Ulceration of the Epiglottis apparently healed by frequent use of the electro-cautery. The epiglottis was a mass of tuberculous ulceration and infiltration. Fifteen cauterisations were applied previous to November, 1909, and 10 since January, 1910. There was now no evidence of active disease in the epiglottis or arytenoids.

Dr. WILLIAM HILL showed a Large Globular Dilatation of the Upper Third of the Œsophagus above a Malignant Stricture in a male aged 47 years. Difficulty in swallowing solids commenced two years ago. A year later the neck was observed to swell up for half a minute after drinking a glass of water, and portions of an ordinary meal were sometimes regurgitated. The swelling in the neck had gradually increased. Under X rays after a bismuth meal the globular pouch-like dilatation was found to extend down to the suprasternal notch, and measured 5½ centimetres in each diameter. It now measured, according to another skiagram, 9 centimetres by 6½ centimetres, and was somewhat pear-shaped vertically. On June 8th an œsophagoscopic examination showed that a tight œdematous ulcerated stricture commenced below the dilatation 26 centimetres from the teeth. This had been dilated by graduated bougies, and a soft rubber œsophageal catheter, 6 millimetres in diameter, fitted with a silver style, had been inserted. The stricture was 3 centimetres in length. The patient was being fed through the catheter, which would be retained for a week to further dilate the stricture, and an attempt would then be made to insert a permanent Symonds's funnel. A dilatation of this size in the cervical and upper thoracic œsophagus following a malignant stricture was very exceptional.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN

Exhibition of Cases.—Treatment of Intussusception in Children.

A PROVINCIAL meeting of this section was held at Portsmouth on June 11th, Dr. E. CAUTLEY being in the chair.

Mr. CHARLES P. CHILDE showed a case of Multilocular Cystic Hygroma of the Neck in a child aged 4 years. A small soft swelling was noticed in the angle between the left clavicle and the anterior border of the trapezius two weeks after birth. This has grown progressively. A fortnight ago the portion beneath the lower jaw became painful and tender, with a rise of temperature to 100° F. This subsided in a week, leaving this portion of the swelling hard.—The case was discussed by Mr. DOUGLAS DREW, who advised removal of the cysts at one operation.

Mr. CHILDE also showed a case of Subperiosteal Resection of the Shaft of the Ulna for Tuberculous Osteomyelitis in a child aged 7 years. There was four and a half months' history of pain over the upper end of the right ulna. A swelling appeared later, which was opened. A skiagram exhibited tuberculous deposit in the ulna. Complete subperiosteal excision of the shaft of the ulna was performed, the bone being sawn through above, below the coronoid process, and wrenched off the lower epiphysis. The case has progressed satisfactorily, and the new ulna formed from the periosteum can be distinctly traced on the screen.—In discussing the case, Mr. H. LETT mentioned a similar case in which he had used a prop to support the bones after resection very successfully.

Mr. CHILDE showed another case of Partial Tarsectomy for Tuberculous Disease in a child aged 5 years. A swelling appeared over the dorsum of the patient's right foot when aged 2 years. This opened and discharged until the time of operation, October, 1908. Incisions on each side of the foot were made and reflexion of the tendons. A large portion of the mid-tarsus, including the disease, was removed with the saw. The child has a very useful foot.

Dr. W. CARLING showed a case of Pseudo-hypertrophic Muscular Paralysis in a boy aged 8½ years.

Dr. L. COLE-BAKER showed a case of Absence of Puncta Lacrymalia (Bilateral) in a child, aged 10 years, who had suffered from epiphora since birth. An attempt was made to pick up the opening in the canaliculus in the left lower lid without success. Both glands were removed through the conjunctiva at the outer angle of the upper lid.

Dr. JOHN T. LEON showed a specimen of Large-celled Sarcoma of Brain. A boy, aged 16 years, was brought up for deafness. There was no deficiency in the auditory apparatus, but very slow cerebration. No paralysis or other motor symptoms were present, except tremors of the hands and nystagmus. There was double optic neuritis.

Dr. LEON also showed a specimen of Peritoneal Growths from a case of Lymphocythæmia, with Blood-slides. A girl, aged 6½ years, was admitted into hospital on May 28th, 1908, for intense anæmia and enlarged spleen and liver. A blood-count on admission showed red cells, 560,000; white cells, 17,500. Post mortem, lymphoid growths were present in practically every organ. The liver weighed 30½ ounces, the kidneys 11 ounces and 9 ounces respectively, and the spleen 5½ ounces, all these organs being the seat of numerous growths.—The case was discussed by Dr. E. I. SPRIGGS.

Mr. C. A. S. RIDOUT related a case of Intussusception of the Small Intestine, containing a Sarcoma of Intestinal Wall, in a boy aged 4 years. An enterectomy was performed and recovery followed. The patient suffered from severe attacks of pain and vomiting, and a mass could at times be felt in the abdomen. At the operation a congested enteric intussusception was found, which was quite irreducible. The whole of the intussusception was resected, and end-to-end anastomosis rapidly performed by suture. Examination showed that the cause of irreducibility was a puckered, indurated growth of the intestinal wall. Microscopically the growth was a round-celled sarcoma. The patient died some months later with secondary deposits in the liver.

Mr. RIDOUT also showed a case of Extensive Injury to the Head in a boy aged 7 years. As a result of injury a large part of the skull in the Rolandic area had been removed. There was pulsation of the scalp, also athetosis of the right hand. The mental power was good.—The case was discussed by Dr. SPRIGGS and Mr. DREW.

Mr. CHILDE showed a child, aged 3 years, on whom he had operated for Ectopia Vesicæ by implantation of the ureters into the rectum.—Mr. DREW, Mr. J. P. LOCKHART MUMMERY, Mr. G. MORGAN (Brighton), Dr. SPRIGGS, and Mr. D. C. L. FITZWILLIAMS discussed the case.

Dr. LEON showed a case of Mental Disturbance after Enteric Fever in a child aged 11 years.—The case was discussed by Dr. F. E. BATTEN.

Dr. C. C. CLAREMONT showed a case of Pemphigus in a child.—The case was discussed by Dr. CAUTLEY and Dr. G. PERNET.

Mr. H. BURROWS showed two cases of Mesenteric Cyst.

Mr. CHILDE opened a discussion on the Treatment of Intussusception in Children, in which he outlined the diagnosis and laid emphasis on the importance of the presence of a tumour in the abdomen as a sign. He pointed out that this sign was practically always present, and that the only condition under which it was not found was when the condition had been present for some days and there was distension. In considering the treatment, he pointed out that operation offered the only certain chance. Resection had given such bad results as to be hardly worth performing. He said that while the results of reduction were good if performed within 48 hours of the onset, the results were hopeless after this time.—The discussion was continued by Dr. CAUTLEY, Mr. DREW, Mr. FITZWILLIAMS, Mr. RIDOUT, Mr. MORGAN, DR. SPRIGGS, Mr. LOCKHART MUMMERY, Mr. BURROWS, Mr. LETT, Dr. PERNET, Mr. W. J. MIDELTON, and Dr. A. V. MAYBURY.—Mr. CHILDE replied.

Dr. CLAREMONT read the notes of a case of Idiopathic Dilatation of the Colon, which was discussed by Dr. CAUTLEY, Mr. LOCKHART MUMMERY, Mr. DREW, and Mr. CHILDE.

THIRD INTERNATIONAL CONGRESS ON SCHOOL HYGIENE, PARIS, AUGUST 2ND–7TH.—Saturday, June 25th, is the date given by the assistant-secretary (Mr. Durrie Mulford) of the organising committee of Great Britain and Ireland by which all applications from English-speaking members should be received at 90, Buckingham Palace-road, London, S.W. The committee is making arrangements for English-speaking delegates and members to stay at some hotels of superior class, and has secured special terms for accommodation and travelling. The fare, including hotel accommodation, will be, if travelling second class, £5 12*s.* 6*d.* each passenger, and if travelling first class £6 2*s.* each passenger. Sunday, July 31st, at 10 A.M., is the time when the party will leave by the boat express from Victoria *vid* Newhaven and Dieppe for Paris. Accommodation will be provided until Friday morning, August 5th, but the railway tickets are available for 14 days. The president of the organising committee is Sir Lauder Brunton, Bart., M.D., LL.D.

Reviews and Notices of Books.

Tropical Medicine and Hygiene. By C. W. DANIELS, M.B. Cantab., M.R.C.P. Lond., Director, London School of Tropical Medicine; and E. WILKINSON, Major, I.M.S., F.R.C.S. Eng., D.P.H., D.T.M. & H. Cantab. With coloured and other illustrations. In three parts. Part I.: Diseases due to Protozoa. London: John Bale, Sons, and Danielsson, Limited. 1909. Pp. 264. Price 7*s.* 6*d.* net.

NO department of medicine has of recent years made greater strides than tropical medicine. New facts concerning the etiology of the diseases of hot countries are year by year established, so that it is well to have presented to us a trustworthy account of these remarkable discoveries. The authors of the volume before us are qualified to give the medical profession such an account. Dr. Daniels is well known as an authority on tropical diseases, having previous to his present appointment as Director of the London School of Tropical Medicine had a long experience in the Colonial Medical Service of British Guiana and Fiji, and he has been ably assisted by Major E. Wilkinson of the Indian Medical Service. When the trilogy is completed we ought to have an inclusive treatise on tropical diseases as they occur in typical portions of the hot countries of the globe.

The subject is treated in a new fashion. Part I., under review, embraces the diseases known to be due to the protozoa, and other diseases, like yellow fever, which are probably due to such organisms. In the second part, diseases due to the higher forms of animal life will be considered, whilst the third will be devoted to bacterial diseases, to the effects of certain vegetable and animal poisons, and to certain diseases the causation of which is unknown or but imperfectly understood. Special prominence has been given to the etiology and prevention of the diseases treated of, and it will be seen that the subject of prophylaxis has been very fully entered upon, the local conditions as well as the general principles having been carefully considered. The important subject of the life-history of the intermediate hosts has been portrayed at some length, as a knowledge of this subject is essential when the rationale of preventive measures is discussed.

The work opens with the consideration of the protozoa. Here we find a lucid exposition of the life of the coccidia, accompanied with an excellent diagrammatic representation of the same. The various clinical features of malaria, its pathology, and its treatment, then receive due attention, and here we are glad to notice that intramuscular injections of quinine are held to be not superior to, if as good as, rectal injections in comatose conditions. The minutiæ of treatment could not be better given. The student will find also a very complete account of all that relates to the examination for the micro-organism of the disease, whilst the preventive measures are fully weighed.

Blackwater fever is next considered. The treatment recommended of this formidable disease leaves nothing to be desired. The authors wisely lay down the rule that the most uniformly successful treatment consists in giving frequent rectal enemata, 6 to 8 ounces at a time, of normal saline solution. A short chapter on piroplasmosis follows, after which we come to yellow fever. Here, again, the subject of prophylaxis is fully entered upon; we do not, however, find any mention of the preventive inoculations carried out some years ago by Dr. Domingo Freire and Dr. Isartier, who reported results that certainly seemed to bear out the efficacy of this method of treatment; for instance, in Rio de Janeiro the mortality was found to be only 1·6 per cent. amongst the inoculated, as against 13·7 per cent. amongst the non-inoculated.

In the chapter on human trypanosomiasis the treatment to be followed out is explicitly laid down. As regards prophylaxis, this is comparatively simple amongst Europeans, but with natives unfortunately this is not so; the most satisfactory consists in deportation of the whole of the uninfected population to an area free from the glossina. The subject of kala-azar follows: the etiology of this disease is fully described. Truly one of the greatest triumphs of tropical medicine has been the discovery of the organism causing it, in which discovery the names of Leishman and Donovan will be ever conjoined.

Oriental sore is described in a short chapter. The treatment, the authors truly remark, is, unless thoroughly carried out, very unsatisfactory. The method employed on the Punjab frontier is not mentioned—viz., that of applying a lead metal disc to the surface of the ulcer—which certainly gives by far the best results in the experience of many. Relapsing fever and tick or African relapsing fever next are described, and here we find a capital table showing the characteristics of the varieties of the fever as it occurs in India, Africa, Europe, and America. We then come to the diseases associated with spirochætæ in the tissues. In treating of yaws the authors, rightly, we think, do not hold it to be identical with syphilis; and they well sum up the matter when they state that the relationship between yaws and syphilis in the sense of both diseases being due to organisms of the same genera is admitted and was predicted, but the relationship is like that between variola and varicella, not that between variola and vaccinia. The final chapter of the book describes the intestinal protozoa. An appendix concludes this first instalment of the work, and in it we are given notable dates regarding the discoveries of the various organisms special to the diseases treated of; a useful statement concerning certain important measurements; a description of ticks; and a subdivision of the more important groups of the diptera.

The student of tropical medicine will possess, judging by the present part, a most valuable addition to his library when the remaining parts of the treatise appear.

Clinical Obstetrics. By ROBERT JARDINE, M.D. Edin., Professor of Midwifery in St. Mungo's College, Glasgow. Third edition. With 108 illustrations and 4 coloured plates. London: Henry Kimpton. 1910. Pp. 745. Price 21*s.*

IN reviewing the second edition of this book[1] we pointed out what a valuable clinical record it was. The third edition has been considerably enlarged and a number of new illustrations have been added. The book is essentially the record of the work and opinions of one man, and there are necessarily many views put forward with which all readers may, and indeed will, not agree. Dr. Jardine, however, has had the advantage of a large clinical experience, and Glasgow is a rich field of practice in operative midwifery. A number of new sections have been added, and the book has undergone a large amount of revision. But when we consider its size it is certainly somewhat disappointing to find how very inadequately some conditions are treated. No doubt this is explained by the fact that a substantial part of the book is taken up with the clinical histories of the cases recorded. Appendicitis is without doubt a not uncommon complication of pregnancy at the present time, and what a dangerous complication it is has been shown by many writers. Dr. Jardine, however, dismisses the subject in a few lines.

The operation of pubiotomy has of late occupied a good deal

[1] THE LANCET, Oct. 27th, 1906, p. 1148.

of attention in many of the obstetric periodicals, but we cannot commend the section dealing with the operation in this work to anyone who desires to obtain a really full account of its difficulties and dangers or clear conclusions as to its results. Dr. Jardine tells us that he has practised it three times, but he does not say what the results have been, and in the same way it is aggravating to find that he does not tell us what have been the results as regards the mothers and children of his series of Cæsarean sections. No doubt the cases he records are all very interesting and instructive, but we must confess we should have been better pleased to be told his mortality-rate, both maternal and fœtal. One of the most important points in connexion with this operation at the present time is the question as to how late in the second stage of labour should it be performed, and what is the mortality-rate of such cases. Statements are made by various authors that in any case in which the membranes have ruptured for some hours the danger is very great, but we are inclined to doubt this statement, and at any rate there is no definite proof of it available at the present time. If it is possible to perform Cæsarean section late in the second stage of labour, as has been done in a number of cases, then one of the arguments in favour of the operations for widening the pelvis disappears, and for this reason accurate information upon this point is very desirable.

A very interesting case, illustrated by an excellent coloured drawing, is recorded of infarction of the cortex of the kidney with complete suppression of urine. A second plate illustrating the same condition is from another case which the author intends to publish in detail later. We notice Dr. Jardine reproduces the statement that in the pyelitis of pregnancy the head or some part of the fœtus presses on the ureter at the pelvic brim. If so, why does the disease usually set in at the fifth month of pregnancy, and why does the undilated part of the ureter not include the whole of the ureter lying below the pelvic brim? If Dr. Jardine will consider this question for himself and not accept the views of other people he will realise that pressure on the ureter cannot be the cause of the pyelitis of pregnancy in the great majority of cases, and if he gets the opportunity of examining the ureters in a fatal case of this kind he will find that the undilated portion, if it is dilated at all, extends but a short distance from the bladder.

Since the book is founded upon the experience of one man, and since such an experience cannot in the ordinary course be complete, there are of necessity some omissions. It is, however, a very useful book, and the clinical histories of the cases contain many lessons for the reader who will take the trouble to read them. The appendix containing the statistics of 30 years' work in the indoor and outdoor department of the Glasgow Maternity Hospital remains unaltered; it is a pity that it has not been brought up to date.

Diseases of the Stomach and Intestines. By R. C. KEMP, M.D., Professor of Gastro-intestinal Diseases in the New York School of Clinical Medicine. With 280 illustrations. London and Philadelphia: W. B. Saunders Co. 1910. Pp. 766. Price 25*s*.

THE author says in his preface that, in view of the excellent works on diseases of the stomach and intestines that have been placed before the medical profession, the publication of a new book on these subjects might almost seem to be superfluous. He proceeds to remark that from a great accumulation of material it is often difficult for the general practitioner to select simple and practical methods, and it is his endeavour that this volume should render service in this special direction.

The earlier chapters of the book deal with the anatomy of the stomach and intestines, the physiology of digestion, the interrogation of the patient, and general methods of physical examination. The consideration of the physiology of the stomach does not include some of the more recent views in regard to the movements of the stomach, but this omission will no doubt be remedied in a future edition of the work. The physical examination of the abdomen is well discussed, and numerous reproductions of photographs aid the written description. The methods of examination of the functions of the stomach are given at length, but the multiplicity of the tests and the complexity of several of them render this portion of the book rather confusing for purposes of actual practice.

The various diseases of the stomach are considered in an able manner, the etiology, pathology, symptoms, diagnosis, and treatment being described in a way which is easy to follow and appreciate. In discussing gastroptosis the author defines this condition as a prolapse or downward displacement of the stomach, right kidney or both kidneys, and other organs of the abdominal cavity, which may be associated with disturbances of the gastro-intestinal tract and pelvic organs, together with various nervous symptoms. He adds: "Nephroptosis is a stigma of gastroptosis." These views are now generally held, and it is also recognised that the condition is more common than was formerly supposed. Professor Kemp draws attention, however, to the fact that it is not the position of the lower border of the stomach which constitutes a "ptosis" but that of the upper border. The determination of the lower border alone is not diagnostic of the condition, and it may merely be evidence of a dilated stomach. Professor Kemp is probably correct in saying that a large number of cases of nephroptosis have been reported with dilated stomachs, the dilatation being imputed to pressure of the kidney on the duodenum, and no investigation has been made of the position of the lower curvature. The portion of the book dealing with diseases of the intestine contains a vast amount of information.

We cannot help feeling that the author has rather defeated his original idea in making the book a complete work of reference rather than a purely practical one for guidance to the general practitioner. As a monograph on diseases of the stomach and intestines, however, we can give it every praise. It is admirably illustrated, reproductions of photographs being unusually numerous.

Geschichte der Medizin. (*History of Medicine.*) By Dr. MAX NEUBURGER, Extraordinary Professor of the History of Medicine in the Imperial and Royal University of Vienna, &c. Vol. II., Part I. Stuttgart: Ferdinand Enke. Pp. 229. Price 5.40 marks.

THE second volume of Dr. Neuburger's "History of Medicine" is divided into two parts, of which the first is now before us and the second and concluding instalment is to appear shortly. The present volume deals with the progress, or rather regression, of medical science during the time between the death of Galen and the end of the fifteenth century. The decline of the Roman Empire was accompanied by a general falling off in medical and other science, and the period here dealt with shows our art at about its lowest ebb. In the absence of any State control charlatanism of all sorts became rampant. Specialism was pushed to absurd extremes, the laity dabbled in medicine, and magic and demonology occupied the place of science. Almost the only advance to which we can point is the establishment of hospitals for the sick and needy, under the influence of Christian teaching. The medical literature of the time shows no fresh observations or discoveries, the books of the period being mere compilations and commentaries on the works of

the older writers, or books of receipts for popular remedies, intermingled with charms and magical formulas. A few names of note stand out in the dreary record. In the fourth century Oribasius, who composed a text-book for students, wrote sensibly on diet and gymnastic exercises in the treatment of disease. Later we have Theodorus Priscianus, whose work has recently afforded Dr. Theodor Meyer an opportunity for writing an excellent book on Roman medicine.[1] Philagrius wrote on affections of the spleen and Poseidonius on those of the nervous system with some degree of merit, and Cælius Aurelianus (fifth century) was a clinician of ability, who studied the methods of physical diagnosis and is noted for his recommendation of a sea voyage as a cure for phthisis. A prominent school of medicine existed at Byzantium in the sixth and seventh centuries after Christ and produced some writers of celebrity, such as Aëtius of Amida, Alexander of Tralles, and Paulus of Aegina. Their works were translated frequently in later times and had considerable influence. We find that paracentesis abdominis was practised at this time and also operations for the radical cure of hernia.

As is well known, the continuity of medical tradition, founded on the system of Galen, was for a time kept up by the famous Arabian school, upon which the names of Rhazes, Abulkasim, Avicenna, and Averroes throw an abiding lustre. The spread of Greek learning to the East was followed by a period of brilliancy in which mathematics were diligently cultivated and the arts flourished. The influence of the former study is seen in the curious attempts of Al-Kindi to apply numerical principles to medicine and to calculate the values of remedies according to the degrees of heat and cold, moisture and dryness, which they contained; while increased manual skill and improvements in the technical details of medical procedure concealed the lack of advance in real knowledge of disease. Rhazes was a good clinician, who applied chemical knowledge to medicine and who is celebrated for his treatise on small-pox; Abulkasim was a distinguished surgeon; of Avicenna, who was an encyclopædic writer and who recognised the infectivity of tuberculosis, it is related that he failed to adapt his mode of life to his own precepts, so that his death was accelerated by his excesses in the service of Bacchus and Venus.

In spite of the somewhat depressing period with which it deals the volume before us contains much that is of the greatest importance to the student of medical history. Professor Neuburger's style is clear and interesting, neither too brief nor too diffuse. We look forward to the publication of the concluding portion of the work with the confident expectation that the whole will form an authoritative treatise on the history of medicine and a monument to the learning and literary skill of its author.

How to Feed Children: a Manual for Mothers, Nurses, and Physicians. By LOUISE E. HOGAN. Philadelphia: J. B. Lippincott Company. 1909. Ninth edition. Pp. 249. Price 5*s*.

NINE editions of this unpretentious little work are sufficient guarantee of its value. Mrs. Hogan does not confine herself to the subject of feeding of infants, but undertakes to advise on the diet of children at all ages under many and varied circumstances. The whole tone of writing, like the advice given, is sound and sensible.

The best chapters are those dealing with the feeding of infants, and proper attention and space are devoted to the preparation and use of modified milk. But the directions for the preparation of modified milk would bear considerable revision, for they are somewhat confused and would be extremely difficult to follow if they were relied upon as a guide. It is to be assumed, however, that the authoress does not intend them to be taken as a complete guide to preparation, but would prefer to leave her readers to the prescription of the physician and the laboratory of the milk expert. Probably Mrs. Hogan's wide experience has convinced her that this is the safest line to take at present, though she says sufficient to induce mothers to direct their attention to the value of modified milk.

Much of the matter in this little volume would appeal more to an American than an English public, especially in the methods and ingredients of cookery. Many of the dishes recommended for the nursery would be very expensive in England, and quite prohibitive to any but the rich. Broiled Porterhouse steaks for the nursery dinner would astonish some housekeepers even in Park-lane. The new chapter on diet for school children and school luncheons is full of suggestion, and might well be studied by social reformers of the day, but the writing is ill-arranged and evidently hasty, and too full of quotations strung together from other writers. The remarks on feeding children when travelling are very judicious; probably more required in the United States than in our little island, parents would find the advice very useful here. We should not at all mind sharing some of the nursery dinners suggested by Mrs. Hogan, especially the white soup, upon which she has sound ideas.

LIBRARY TABLE.

The Sale of Food and Drugs Acts, 1875 to 1907, and Forms, Regulations, Orders, and Notices issued thereunder, with Notes and Cases, together with an Appendix containing the other Acts relating to Adulteration, Chemical Notes, &c. By Sir WILLIAM J. BELL, LL.D., of the Inner Temple, Barrister-at-Law. Fifth edition. By CHARLES F. LLOYD, of the Inner Temple and Midland Circuit, Barrister-at-Law. The Chemical Notes revised and enlarged by R. A. ROBINSON, of the Middle Temple, Barrister-at-Law. London: Butterworth and Co. and Shaw and Sons. 1910. 8vo. Pp. 386. Price 8*s*. 6*d*. net.—The Sale of Food and Drugs Act, 1875, supplemented by two amending Acts and two relating to the sale of margarine and butter, contains the bulk of the law relating to the adulteration of food. There are older statutes unrepealed as to bread, but the Bread Acts of 1822 and 1836 are not often called into use, because the Sale of Food and Drugs Acts provide heavier penalties and do not leave open the defence that the offender had not a guilty knowledge when he sold the defective article. The earliest repealed predecessors of the existing statutes provided against the adulteration of coffee, tea, hops, and beer, the first of these, which affected coffee, having been passed in 1718, when King George I. was on the throne. These commodities were luxuries of the rich, marked out by their costliness for the exploitation of the fraudulent. To-day it is the cheaper foods of the poorer classes which are the objects of the legislature's solicitude, and the "Butter and Margarine Act, 1907," is one of the recent amendments of the law which prompted a new edition of Sir William Bell's useful text-book. It may be noted that this statute contains a new and wider definition of margarine as "any article of food, whether mixed with butter or not, which resembles butter and is not milk-blended butter." The old definition spoke of substances "prepared in imitation of butter." In addition to the Act referred to, Mr. Lloyd, the present editor, has had to record more than 50 decisions of superior courts affecting his subject and a substantial number of departmental circular letters containing information and recommendations for the benefit of local authorities. Important among circulars of comparatively recent date may be mentioned those of 1906, which recommend steps

[1] See THE LANCET, June 18th, p. 1700.

to procure the disuse of all preservatives in milk. Accurate knowledge of recent decisions is, of course, necessary for those concerned with the enforcement of Acts of Parliament, and the editing of Mr. Lloyd has placed such decisions in a compendious form, with a sufficiency of judicious comment. A note on the subject of drugs and their adulteration points out that, although a Select Committee, considering an amending Bill in 1879, recommended the adoption of the British Pharmacopœia as a standard for drugs in proceedings under the Food and Drugs Acts, their advice was not carried out. To a limited extent the British Pharmacopœia may no doubt be used as such a standard, as, for example, when a compound named in the Pharmacopœia is asked for by the title under which it there appears, and when the Pharmacopœia states exactly what the constituents of the article in question should be and in what proportions they should be combined.

The Public Health (London) Act, 1891, with an Appendix containing Statutes affecting the Metropolis. Second edition. By ALEXANDER MACMORRAN, M.A., one of His Majesty's Counsel, one of the Editors of "Lumley's Public Health"; and E. J. NALDRETT of the Middle Temple, Barrister-at-Law. London: Butterworth and Co. and Shaw and Sons. 1910. Pp. 569. Price 20*s.* net.—Messrs. Macmorran and Naldrett have prepared a second edition of a work of great usefulness which brings it up to date, or, as they would apparently express it, "down" to date. The Public Health (London) Act, 1891, has not required any extensive revision or amendment since its passage through Parliament nearly 20 years ago, and the statutes affecting it which have become law during that period take the form, to a great extent, of London County Council (General Powers) Acts, the relevant portions of which are contained in a not over-voluminous appendix. The cases decided under the main Act, which have to be noted under the various sections affected, accumulate steadily, as is natural in the circumstances of growth and development characteristic of modern London. Thus we find that 18 pages of notes are devoted to decisions relating to the definition of "drains" and "sewers," very important problems for discussion when questions as to who should defray the costs of maintenance are concerned. The definition of and distinction between drains and sewers were apparently left for inference and for elucidation in the law courts by those who framed the Public Health (London) Act, 1891, and as in the case of some other matters so left to take care of themselves in Acts of Parliament, the legal profession at all events can have no cause to complain. A late decision may be noted of a point for which the Act itself might well have provided, in the case of J. Lyons & Co. *v.* The Lord Mayor, &c., of London (1909), where the local authority sought to treat as a case of trade refuse the removal from a restaurant of the débris which, in the case of a private house, would be "house refuse." At present it seems to be established that if the refuse to be removed is house refuse in character the mere fact that it has been produced in the carrying on of a trade does not make it trade refuse. The name of Mr. Macmorran is so well known in connexion with the law of local government and administration that it is hardly necessary to say that a book on public health, edited by him, is an authoritative guide to the subject with which it deals; this second edition will occupy the high position as a text-book hitherto occupied by the first.

CAMBRIDGE MEDICAL GRADUATES' CLUB.—In consequence of the death of his late Majesty King Edward the annual meeting and dinner of the club will not be held as usual in July, but are postponed until November.

METROPOLITAN HOSPITAL SUNDAY FUND.

UP to Thursday morning, June 23rd, about £29,000 had been received at the Mansion House, the collections at the churches generally showing an increase. Among the amounts are:—

	£	*s.*	*d.*
Mr. William Herring	1000	0	0
Holy Trinity, Chelsea	460	0	0

THE LANCET.

LONDON: SATURDAY, JUNE 25, 1910.

Some Medical Aspects of Proposed Poor-law Reform.

AN interesting paper was read by Dr. MAJOR GREENWOOD before the Medico-Legal Society on May 24th, in which he discussed the past history of the Poor-law and some of the proposals of the Royal Commission in their relation to the work of the medical man both in and outside the Poor-law medical service. If we take Dr. GREENWOOD'S last paragraph as summarising the conclusions which he desired to lay before the Medico-Legal Society they are that reform in the administration of our charities "should go hand in hand with Poor-law reform and that this is much more likely to take place under a well-considered reconstruction of our present Poor-law than by its ruthless breaking up." He considers in this connexion that the revenue from charitable sources is so great that "if our charities were properly organised and a stop put to the numerous impositions upon them" charity would step in to aid those who otherwise would come under the destitution authority, and that the Poor-law would suffice for the assistance of those not so prevented from having recourse to it. This appears to be an opinion in support of the scheme of Mr. CHARLES BOOTH, the best plan yet put forward for making use of the existing machinery. The difference between such a scheme and those propounded by the majority and by the minority of the Royal Commission is that these both contemplate the inauguration of a system of organised effort independent of the pecuniary relief of destitution when it has occurred, and having as an object the prevention of the circumstances in which Poor-law relief, as we understand it, is required. This prevention Dr. GREENWOOD believes to be impossible, at any rate upon any large scale.

The preventive aspect of the question involves the general problem of reform, many phases of which have been discussed recently in our columns. Of these, one of the most interesting is the question whether in the future the treatment of disease, as an object of public assistance, should be transferred to the hands of the sanitary authority. The majority of the Commissioners, with whom Dr. GREENWOOD must here be in accord, say "No"; the minority are responsible for, and warmly support, the suggested combination of services. Dr. GREENWOOD, in protesting against anything that would include the risk of an extension of free medical aid, claims to establish a distinction of principle between such existing free services as the sanitary service, vaccination, and education, and the provision of medical treatment as part of the sanitary service. He suggests that the first three are instituted primarily for the good of the State, and only in a secondary degree for that of the individual. The medical attendance accorded under the Poor-law, he appears to think, is prompted primarily by consideration for the individual. We cannot appreciate the distinction which he draws. The actual attendance of the Poor-law medical practitioner affects the individual precisely as does that of the public vaccinator or the school teacher, but the object before the eyes of the Royal Commissioners who signed either report, as of any legislative change which may follow, will be the good of the community. Whether the combination of medical and sanitary service would prove advantageous to the public in practice is another matter not easily to be settled without a practical test. The proposal has, however, a great deal to commend it, and it is not necessary to assume either, as its opponents are prone to do, that it would necessarily extend widely the provision of free medical aid or, as its advocates seem to do, that there could be no room in such a scheme for a part-time medical officer of health. The Minority Report contemplates such an extension as part of its general policy, but the combination of sanitary and medical services is not altogether inconsistent with the establishment of a public assistance authority as contemplated by the Majority Report, or, indeed, with the retention of the present Poor-law system in an amended form. It might be a difficult thing to organise a combined service working either under one authority (a health authority) or under the joint supervision of two authorities (that of public assistance and the sanitary authority), but that is not the same thing as to say that it is impossible, or that it might not have practical advantages to outweigh its drawbacks.

The question of the general effect upon the medical profession of carrying out the proposals of one or other of the reports of the Royal Commission has been frequently discussed. Dr. GREENWOOD raises it again and is of the opinion that "if the medical recommendations either of the majority or the minority are carried out, it means disaster for that profession." If by the medical profession is meant those engaged in private practice it appears that considerable disturbance and loss to individual practitioners might be the result of carrying out in its entirety and with complete success either scheme. At the same time, in considering this we must bear in mind that both majority and minority aim at aiding the work of the Poor-law by keeping out of poverty due to ill-health the greatest possible number of workers. Both parties intend, in other words, that there shall be an important increase in the amount of work done by the medical profession as a whole among the working classes, and also that the increase shall be paid for in part or wholly out of public moneys. This may imply disturbance of existing conditions of private and official medical practice, but it can hardly bring about disaster to the medical profession, and it certainly is not desired or expected that it should do so, either by the majority or the minority. Those who wish to study the case for a medical service such as the minority would approve put with the force of an able advocate will find it in a paper read little more than a year ago[1] by Mr. GEORGE BERNARD SHAW to the society

[1] THE LANCET, Feb. 27th, 1909, p. 617.

which Dr. GREENWOOD has now addressed upon the opposite side. We do not say that we agree with Mr. SHAW, but he advocates his views so as to leave no mistake as to his meaning. Political prophets do not anticipate drastic change in Poor-law administration occurring in the near future, and everything points to minor administrative changes and to the reform of existing circumstances. These require to be watched attentively by the medical profession and particularly by those engaged in the service of the Poor-law in order that their interests may be equally considered with those of the class from which their patients are derived. The discussion of legislation directly based upon the reports of the Commissioners is useful, but until a Bill is before Parliament and the public such discussion has to cover a field of possibilities too wide for practical debate.

The Choice of Operation for Prostatectomy.

THE interference of an enlargement of the prostate gland with the emptying of the bladder has long been recognised and the seriousness of its consequences has been seen. Early in the nineteenth century Sir EVERARD HOME described what he called the third lobe of the prostate, and pointed out its importance in interfering with the urethral opening, though it is possible that his opinions were really founded on notes made by JOHN HUNTER. Although it has been more recently recognised that this so-called third, or median, lobe is nothing more than a projection from the lateral lobe, and that its removal will not in most cases suffice to render clear permanently the channel of exit from the bladder, yet it was probably due to the prominence of this lobe that attempts were first made to free the urethra by operative measures. Up to some 25 years ago little had been done for the treatment of these cases of enlarged prostate beyond the recommendation of regular catheterisation, and in those days, when the full importance of sepsis as a cause of fatal renal disease was not fully appreciated, "catheter life" led inevitably to septic cystitis and septic inflammation of the kidney, ending in death.

The first real attempt at the removal of the prostate was made by MCGILL of Leeds, who in 1889 published a paper in which he showed that the obstruction produced by an enlarged prostate was almost entirely caused by the portion projecting into the bladder, for there may be much projection towards the rectum with no obstructive symptoms. Moreover, he showed that other forms of enlargement than the middle lobe might cause obstruction. Further, his results made it clear that it was possible by the suprapubic route to remove portions of an enlarged prostate with comparative ease, and with a mortality ranging from 15 to 20 per cent., and in this way to make it once more feasible for the bladder to empty itself. This partial prostatectomy by the suprapubic route was a decided advance on the treatment previously employed, and to MCGILL must be assigned the credit of having done the pioneer work in this field. Some few surgeons followed MCGILL'S instructions, but the operation did not receive much recognition, and though the mortality could not be considered very heavy, if the serious nature of the condition was taken into account, yet, what was of far more importance, the success was in many cases by no means complete. Many surgeons felt consequently that it was hardly worth while for the patient to be subjected to so great a risk for so doubtful a benefit. Other methods of treatment had a transient popularity. Orchidectomy and vasectomy were brought forward as less likely to be harmful, and for a time they were acclaimed as definite advances in the treatment of enlarged prostate, and a somewhat sharp discussion took place as to the priority of invention. But the rival claims have now been all put aside, for these methods were shown to be useless. From time to time attempts have been made to extract portions of an enlarged prostate through the urethra; some of these methods have been remarkable rather for their ingenuity than for their success. It is so seldom that the mere removal of a small projection can lead to the re-establishment of a complete functional activity of the bladder that, as might have been expected, these methods have never obtained a wide repute and are now almost forgotten. Enucleation of the whole enlarged prostate by the suprapubic route may be looked upon theoretically as a mere advance on MCGILL'S operation, but the difference in the results, the ease of its performance, the diminution of mortality, and, in most cases, the completeness of its success mark it out clearly from the operation from which it was derived. To P. J. FREYER is undeniably due the credit of the popularising of this method of removal of the prostate; he has performed it now in several hundred cases with a mortality of less than 7 per cent., and the operation which is now known as suprapubic prostatectomy is the operation advocated by FREYER. We need not consider whether it is indeed the whole gland that is removed or whether merely large adenomatous masses are enucleated, some of the real gland substance remaining spread out in what has been called the capsule. This is a mere theoretical point of no practical importance, and whatever the true answer may be it cannot affect the desirability of the operation. REGINALD HARRISON seems to have been one of the first to advocate strongly the perineal route for the removal of an enlarged prostate and many methods have been described, differing from one another in the incision required, the instruments employed, and the exact mode of enucleation. It cannot be disputed that by the perineal route it is possible to remove most, if not all the forms of enlarged prostates, and especially those in which the enlargement has been in the direction of the rectum, and at the present time it may be said that only two methods of removal of enlarged prostate are before the surgical public. These are enucleation of the gland through a suprapubic incision and enucleation through an incision in the perineum.

It is not by any means easy to give a decision as to the relative merits of these two operations, but it is curious and interesting to note that in the discussion of this question different countries take different sides. In the British Isles there is something closely approaching to unanimity as to the merits of the suprapubic operation. Much of this may certainly be ascribed to the eloquent advocacy of FREYER; still more, however, is due to the excellent results which have followed the operation in the hands of those who have ventured to undertake it. In France, Germany, and the United States of America the perineal

operation is more widely practised than its competitor. It is difficult to offer any very certain explanation of this curious difference of opinion; time will, it needs no saying, assimilate before long international procedure on this matter, but for the present opinion is fairly sharply divided. The exact mortality of the operations differs in different hands, but when we compare the statistics of the best operators on both sides there is little to choose between them as to the death-rate. There are many small and unimportant arguments which may be put forth for one or other of the operations, but in most of these arguments their weight cannot suffice to turn the scale. But one or two may be worthy of mention. When the enlarged prostate projects boldly into the cavity of the bladder there can be no question in the mind of surgeons who have performed this operation that the method of enucleation by the suprapubic route is simple, safe, and effective. In fact, it is in these massive intravesical growths that the suprapubic operation manifests its superiority most clearly to those who are practically acquainted with it. The case is, however, far different when the surgeon has to deal with small, hard, fibrous prostates, presenting little obvious prominence on the vesical aspect. It is extremely difficult to enucleate these by a finger introduced from above. In vain the surgeon strives to strip the capsule from the gland, his utmost efforts serve but to tear away the hardened tissue piecemeal; and, in fact, it must be accepted that there are some fibrous varieties of enlarged prostate which do not admit of true enucleation, and that surgeon is well advised who declines to remove suprapubically a prostate which does not, when viewed through the cystoscope, show an obvious enlargement towards the interior of the bladder. On the other hand, when the growth of the prostate has proceeded mainly in the direction of the rectum, the perineal route commends itself to the discriminating surgeon as admirably calculated for an efficient removal; for these cases, which are most difficult to the operator who proceeds by the suprapubic incision, present the fewest difficulties to the surgeon who chooses the perineal route. This, then, may be laid down as representative of the present position. Should the growth show manifestly a tendency to enlarge mainly in the direction of the bladder, a suprapubic cystotomy offers the best direction from which to attempt its removal; while, on the other hand, a growth proceeding towards the rectum clearly suggests a perineal incision. And, if the enlargement be but slight and firm in consistency, the perineal route offers a better chance for its removal. It is hardly necessary to discuss the question of the double operation, an incision being made both suprapubically and in the perineum, for although it does diminish the difficulties inherent in either method, the very definite increase in the risk, as shown by the death-rate, is of itself sufficient to negative its adoption. Whatever, then, may be the verdict of the future as to the choice of operation, we can at least be certain that in the last 20 years a very decided advance has been made in the treatment of a most troublesome and serious condition. Restoration to almost complete health has replaced a long, tedious employment of catheterisation, which was wont only to end in a painful death.

The Dissemination of Diseases by Dairy Products and its Prevention by Pasteurisation.

THE circulars which are issued from time to time by the Bureau of Animal Industry of the United States Department of Agriculture have one special feature in common apart from their high scientific value, and that is their clearness and directness. Circular No. 453, which has recently been published, deals by means of a series of short papers with the question of preventing the spread of disease by dairy produce, and most attention is directed to the difficult subject of tuberculosis, as well as incidentally to enteric fever and other milk-borne diseases. The first paper is by Dr. G. LLOYD MAGRUDER of Washington, who supplies some telling plates relative to unwholesome cow-houses, ungroomed cows, and deposits from dirty milk, and who lays great emphasis upon the importance of the pasteurisation of milk as an immediate preventive measure. He also furnishes a chart purporting to show the decreased mortality of children in the District of Columbia since the enactment of the milk law of 1895. The chart shows a well-defined fall, but we should have liked some contrast diagrams from other districts where no such milk law has been in operation. The fall in the infantile mortality of several of our large towns has been well marked during recent years, but it would, we think, be difficult to account for it fully and in a satisfactory manner except, perhaps, by including meteorological conditions. No milk law has been in operation in this country which might be regarded as having caused the fall. But Dr. MAGRUDER has evidently been influenced by some of KOBER's observations relative to 330 milk-borne epidemics. Of the total, 243 were recorded by English authors, 52 by American, 14 by German, 11 by Scandinavian, and 5 each by French and Australian, the enormous preponderance of outbreaks in England being ascribed by KOBER to the fact that the English, like the Americans, usually consume raw milk, while on the continent of Europe milk is usually boiled before use. We must confess ourselves not wholly satisfied with this inference, as we should rather attribute the English preponderance to the fact that we in England have been alive to the danger for very many years and have possessed a system of notification of diseases which has enabled us at once to put our finger on the cause. But in support of KOBER'S view, Dr. MAGRUDER refers to the outbreak of enteric fever which occurred in Cassel in August, 1909, in which it was found that only those members of the household who had partaken of the milk uncooked were attacked, whereas all those who consumed the same milk scalded or boiled remained well.

The cattle of America are not, it is alleged, so commonly affected with tuberculosis as those of Europe, but, notwithstanding this, the Bureau of Animal Industry found that 33 per cent. of the centrifuge slime examined at public creameries showed tubercle bacilli. Dr. J. R. MOHLER lays stress upon the risk of contracting tuberculosis from milk, and draws attention to the fact that the figures as regards primary intestinal

tuberculosis in children may range from 2 per cent. (BOVAIRD), to as high as 45·5 per cent. (HELLER) of the tuberculous cases examined. He reminds his readers that there is conclusive evidence to show that tuberculous infection may be taken through the intestinal tract without leaving any lesion in the abdominal cavity, the first tuberculous deposit being found in the lungs or the thoracic glands, a circumstance which raises the question as to how far pulmonary tuberculosis in infants, even in the absence of intestinal lesions, may not be due to tuberculous milk. If this be so, the fact that from 15 to 25 per cent. of all milch cows in the District of Columbia are tuberculous is a very serious matter. Dr. MOHLER then goes on to deal with the risk of tuberculous infection from butter and cheese, both of which have been shown experimentally to be capable, if made from tuberculous milk, of causing tuberculosis in guinea-pigs. His chief recommendations are that milk should either come from tuberculin-tested cattle or be efficiently pasteurised, and that all milch cows on dairy farms should be tattooed or otherwise marked. To the same interesting circular Dr. E. C. SCHROEDER, superintendent of the experimental station at the Bureau of Animal Industry, furnishes some very cogent reasons why we should protect ourselves against infected dairy products. He points out that tuberculosis has a unique place among pathological conditions, inasmuch as it is one of the relatively small number of infectious diseases that attack more than one species of animals, and that it is the only known infectious disease from which no vertebrate species is immune. Although tuberculosis has received more attention than any other disease from investigators in pathology, bacteriology, and hygiene, our knowledge of it is in some respects extremely rudimentary. As he observes, we know so little about its period of incubation that we are unable to determine whether those are right who believe that tuberculosis arises from infection that may enter the body at any time of life, or those who believe that it almost constantly develops from latent tubercle bacilli taken into the body during the milk-drinking period of life. This is perhaps the crux of the whole tuberculosis problem, and it ought probably to be accorded more weight by those who are inclined to attribute all tuberculosis to discovered exposure to human infection.

On the questions of infectivity and hereditary influence the report contains some valuable remarks. We know, Dr. SCHROEDER says, that the revelations of post-mortem examinations prompt the conclusion that few persons escape the tubercle bacillus, while it is agreed that tuberculosis develops with peculiar frequency when the drain on the mental and physical forces is greatest rather than during periods following exceptional exposure to infection. But we know further, says this authority, that the children of tuberculous parents succumb to tuberculosis—not necessarily as children—more commonly than those of healthy parents. This is a disputed conclusion. With regard to infectivity Dr. SCHROEDER thinks that tuberculosis is not so common amongst persons unusually exposed to infection as we might expect; and that men with tuberculous wives and women with tuberculous husbands, when their family records as regards tuberculosis are clean, contract the disease so rarely that their presumably intense exposure cannot be said to infect them more frequently than persons in general become infected. The tubercle bacillus is, he believes, peculiar in that it is prone to remain alive and virulent for long periods in circumscribed, closed tuberculous lesions, and that it may remain in the body indefinitely without causing conditions which may be identified as tuberculosis. Finally, he argues that tubercle bacilli in dairy products are either in a fresh or well-preserved state, and that they are directly introduced into the body with the use of indispensable articles of food, while tubercle bacilli in sputum are exposed to conditions which he considers almost certainly sterilise them before the sputum can be pulverised and float in the air. Whatever chances adults may be disposed to take as regards exposure to tubercle bacilli in milk and dairy products, we must, he pleads, consider our obligations to the children in the matter of pure milk, and he also is obviously in favour of pasteurisation.

This report is of peculiar interest in that it shows how strong is the feeling in scientific circles in America as to the danger of contracting tuberculosis from milk. Notwithstanding the late Professor KOCH'S arguments at the Washington Congress in 1908, it is clear that the American pathologists at the Bureau of Animal Industry are satisfied as to the danger to be anticipated from milk, and have decided that pasteurisation is one of the best means of mitigating such dangers, at any rate until greater advances have been made in the direction of securing a pure milk-supply.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ELECTION OF MEMBERS OF COUNCIL.

THE Fellows of the Royal College of Surgeons of England will have, at the approaching election of members of the Council, a simpler task than usual, for the number of candidates exceeds by one only the number of vacancies in the Council, there being four vacancies and only five candidates. On most other occasions when four vacancies have existed the number of candidates has been much greater. In 1893, for the four vacancies 11 Fellows competed; in 1900, for the same number of vacant places, no fewer than 12 candidates offered themselves, and in 1902 there were eight candidates for the four vacancies. The nearest approach to the present situation obtained in 1905, when six candidates appeared for four vacancies, but one of these withdrew his candidature after the nomination but before the election, so he received some votes. In 1908 the fact that four vacancies existed induced eight Fellows to compete, and it is therefore difficult to give any plausible explanation of the fact that so few candidates have come forward this year. Three of the vacancies have arisen in the natural course of events, except that Mr. H. H. Clutton died shortly before the end of his term of office. The fourth vacancy is caused by the resignation of Mr. G. A. Wright of Manchester, whose term of office would have come to an end

in 1914. As a consequence of this mode of origin of the fourth vacancy, the successful candidate at the present election who receives the lowest number of votes will become the substitute member of the Council for Mr. Wright, and he will therefore have to vacate office in 1914. The five candidates are Mr. C. B. Lockwood, Mr. Bilton Pollard, Mr. Charles A. Ballance, Mr. J. Ernest Lane, and Mr. J. Bland-Sutton. Mr. Lockwood is at present a member of the Council of the College, and as he was elected in 1908 as a substitute for Mr. Howard Marsh, who had resigned, Mr. Lockwood has served for only two years on the Council. We consider that he thoroughly deserves to be reappointed for a full term of eight years. The other member of Council whose term of office has come to an end is Mr. John H. Morgan, but he does not intend to apply for re-election. Mr. Morgan has done much good service on the Council, and he will certainly be greatly missed. To take the remaining candidates in order of seniority: Mr. Bilton Pollard passed his Fellowship examination in 1881. He is surgeon to University College Hospital and is at present a member of the Court of Examiners of the Royal College of Surgeons, and we feel sure that his sound common-sense as well as his surgical knowledge and ability would make him a valuable addition to the Council. Mr. Ballance obtained his Fellowship in 1882, and he is surgeon to St. Thomas's Hospital. He is specially known for the large amount of work he has done on the surgery of the ear, and he has devoted much attention also to the surgery of the brain. Mr. Lane also obtained his diploma of Fellowship in 1882. He is surgeon to St. Mary's Hospital and to the Lock Hospital; he is also a member of the Court of Examiners of the College. Mr. Bland-Sutton passed his Fellowship examination in 1884. He is surgeon to the Middlesex Hospital and to the Chelsea Hospital for Women. He has done excellent work in pathology and he is well known as a general and gynæcological surgeon. The problem before the electing Fellows is to choose from these five the four whom they consider the best to serve on the Council, or rather, as Mr. Lockwood should certainly be returned, the problem is to choose three. Of the four candidates under discussion, three have already appeared as candidates for the Council on one or more occasions. Mr. Bland-Sutton has on four occasions appeared as a candidate, and twice he has received more votes than any other unsuccessful candidate. We consider that Mr. Bland-Sutton, from his position in the profession, certainly deserves a seat on the Council of the College, and we hope that he will prove successful at the election. Mr. Bilton Pollard and Mr. Ballance have also been candidates already, but Mr. Ernest Lane has not hitherto competed for a seat. All three are widely known and we should not be surprised to find any one of them successful. If Mr. Ernest Lane should not succeed on this occasion we have little doubt that he will poll enough votes on a subsequent occasion to give him a seat on the Council. We have compiled the following list in order to show the dates on which the several members of the Council will retire:—In 1911: Mr. H. T. Butlin (President, first elected 1895), Mr. Clinton T. Dent, and Mr. G. H. Makins. In 1912: Mr. S. F. Eve (first elected 1904), Mr. A. A. Bowlby, and Mr. H. G. Barling. In 1913: Mr. R. J. Godlee (first elected 1897), Mr. E. Owen (first elected 1897), and Mr. C. H. Golding-Bird. In 1914: Sir Henry Morris (first elected 1893) and Mr. F. Richardson Cross (first elected 1898). In 1915: Mr. C. W. Mansell Moullin (first elected 1902), Mr. W. Bruce Clarke, and Mr. Charters J. Symonds. In 1916: Mr. A. Pearce Gould (first elected 1900), Mr. W. Arbuthnot Lane, and Mr. W. F. Haslam. In 1917: Sir W. Watson Cheyne (first elected 1897), Mr. W. Harrison Cripps (first elected 1905), and Mr. R. Clement Lucas (first elected 1901).

MEDICINE AT THE WORLD MISSIONARY CONFERENCE.

THE great assembly of missionaries, representing all creeds and denominations, convened at Edinburgh to promote "the evangelisation of the non-Christian world," has more than justified its programme. Indeed, it may be said to be "twice blest," not only in the object it had at heart, but also in the reaction for good it has had upon itself. Fraternity in coöperation has been its distinctive note, and will continue, it is fondly expected, to minimise sectarian differences and make for that unity the absence of which has been not only a stumbling-block *per se*, but one of the main obstacles to that Christianising of the heathen which each sect aspires to bring about. One feature of its transactions has special interest for us—the admission, freely and frankly conveyed, that mission effort has no more powerful and effective auxiliary than the healing art. That effort has seen the futility of merely dogmatic inculcation in turning the non-Christian subject to the true faith. We never hear nowadays of the zeal, outrunning discretion, which would flog a little Hindoo for not listening to Paley's "Evidences." Only when the missionary has wrought on the lines of his great Exemplar, and while concerning himself with the soul has done his best for its tenement the body, have his labours fructified in conversions at once genuine and enduring. To the devoted Jesuit pioneers of the sixteenth century credit is due for the first effective departure in this direction, and the church they represented has not been forgetful of their initiative, witness (*inter alia*) the wonderful successes of Father (afterwards Cardinal) Massaia in the Galla country. Other churches have followed suit—nowhere more fruitfully than in the region which takes its name from the medical explorer, David Livingstone, who, unconsciously it may be but none the less surely, was laying deep and solid the foundations of that dominion which, before the century is out, will assert its "civilisation" from the Cape to Cairo. In the light of these considerations it is gratifying to note, from statistics laid before the conference, that of the regular missionaries numbering 5522 there are 641 men and 341 women medically trained and duly qualified, while, as part of the "missionary plant" (so to speak) there are in working 550 hospitals and 1024 dispensaries. In-patients received in these hospitals during the last statistical year amounted to 164,245; dispensary "treatments" during the same twelvemonth were no fewer than 4,231,635; out-side patients visited in that period were 144,708—the total individual patients amounting to 4,272,468 and the total treatments to 7,501,013. Surgical operations, we are further informed, during the year were 157,655, while the medical schools and classes at which the missionary can qualify or supplement his qualification numbered 111. Of students (including 136 women) there were 830; schools and classes for nurses amounted to 92, at which the students were 628. In addition to the medical organisation properly so-called, there were ancillary institutions, such as orphanages, 255 in number, accommodating 20,206 inmates; 88 leper asylums and hospitals with 6759 patients; 21 homes for untainted children of lepers, with 567 under surveillance; institutions for the blind and the deaf mute numbered 25, with 844 pupils; 21 were the rescue homes, with 856 inmates; 103 the "opium refuges" and 2548 inmates; 15 the homes for widows, entertaining 410; and 28 the industrial homes, with 1788 employees. Such is the advance estimated up to the present moment in the organisation, philanthropic and medical, which now constitutes an active contingent of the great missionary army, and the contribution it makes to the successful conduct of the campaign not only justifies its intervention but calls loudly for further additions to its *personnel*

and further extension of its equipment. No movement of the twentieth century bids fairer to enlighten, to elevate, and to "civilise" its derelict populations in the partially explored continents than that which has taken its newest departure in the northern metropolis. Like all systematic efforts for man's amelioration it has, like the "charity" that inspires it, "begun at home"; laying aside sectarian prejudice and self-centred pre-occupation to give undivided thought and effort to the grand cause; and, not less reassuring as a condition of ultimate success, holding out the right hand of fellowship to a sister profession whose coöperation has already so powerfully contributed to the consummation it would otherwise have seen hopelessly deferred.

EXCESSIVE WATER CHARGES IN THE CITY OF LONDON.

THERE can be little doubt that the revised charges made for water services by the Metropolitan Water Board are in not a few instances opposed to common sense. The actual consumption of water need bear no relation whatever to the rateable value of many of the great buildings of London. In a good many instances it is even probable that water is not in great demand as a domestic necessity and yet the charges based on rateable value would be very high. Take, for example, the great banking houses, the insurance offices, not to mention the stockbrokers' offices and many others in which the domestic need for water must be very small, although hundreds of men may be employed in these buildings. The water they require for drinking purposes, or for the flushing of drains, can scarcely be comparable with the water used in a domestic dwelling for the bath or for cooking purposes. It is conceivable, in fact, that the family who live in a house in the suburbs rated at, say, £40 per annum, and which pays therefore a rate represented by 5 per cent. upon this amount for the water supplied, would use considerably more water in a day than passes in the same time the taps of a great commercial house in the heart of the City. There must be many cases in which the use of water in a palatial office of business is very small, and yet the bill may amount to a hundred pounds. This is surely a silly anomaly which is not incapable of adjustment. The revised charges have, as a matter of fact, pressed so hard upon some institutions in the City that they have had recourse to sinking artesian wells in order to render themselves independent of the Metropolitan Water Board's supply. The question is discussed in the recent report of the medical officer of health of the City of London (Dr. W. Collingridge) to the sanitary committee, who refers to the figures which have been published in the daily press, claiming that in consequence of the present high charges of the Water Board great economy can be effected by sinking an artesian well and drawing water therefrom. One example is quoted in which a large hotel was paying £900 a year water rate. A well and pumping plant were installed at a cost of £800, and the total cost of running this plant, including repairs, has been found to be £200 a year, and thus a saving of about £700 per annum appears to have been effected by a capital expenditure of £800. The question is, Will the supply to the artesian well continue to be adequate? If not, then once more the hotel company will be compelled to return to the old rates and must write off the money sunk in the well as a loss. Moreover, if there should be any extension of this policy the water-supply existing in the basin of London threatens to be depleted. Outside this area, again, the Water Board has wells. The position may thus become a very serious one. Apparently, except for a salinity and softness (in some directions advantageous qualities) which this artesian well water exhibits, there is nothing on the showing of chemical analysis against its fitness for drinking purposes. When it is considered that great financial corporations are compelled to sink their own wells in the heart of the City of London because the water charges by the authority appointed by Parliament to supply this common need are highly unreasonable, it is time, we think, that such a stigma on our economical and sanitary administration was removed. It is a significant fact, at all events, that only 14 wells were sunk in the City of London between the years 1836 and 1907, while no less than 22 were constructed in the years 1908 and 1909. It may be added that the Bank of England, the Mint, and the Houses of Parliament have their own wells, and are therefore independent of the Metropolitan Water Board's supply.

SUDDEN DEATH IN CONNEXION WITH THE USE OF MOMBURG'S METHOD OF HÆMOSTASIS.

TWO years ago Momburg described in the *Centralblatt für Chirurgie* (June 6th, 1908) a method which he had devised for preventing or stopping hæmorrhage in the lower half of the body by tightly constricting the body at the waist by means of a rubber tube. This method has been widely employed both by gynæcologists and surgeons, and many reports have been published of its great value, up to the present some 200 applications having been recorded. In the May number of the *Revue de Chirurgie* Professor G. Gross and Dr. André Binet of Nancy have described a case in which death occurred in connexion with Momburg's technique. For the most part the use of this mode of hæmostasis has been unattended with danger. It has, almost always, a temporary action on the circulation and on the heart, for at the time when the tube is applied and when it is removed there is an increase in the frequency of the heart beats, and the pulse may reach 150 or even 180 beats a minute. However, several other troubles have been recorded; some of these, such as paralysis of the bladder and of the rectum mentioned by Pagenstecker, and painful cramps of the lower limbs observed by Höhne, were probably caused by pre-existing conditions, but some troubles seem to have been directly due to Momburg's method. These are the discharge of blood-stained fluid from the mouth and nose as recorded by Willems, hæmoptysis as observed by Guinard, and hæmorrhage from the bowel as in a case recorded by Pieri. These may all be put down to the increased pressure in the large arteries and veins of the abdomen. The most troublesome symptoms, however, are those connected with the heart. A patient under the care of Trendelenburg had mitral insufficiency for 12 days after the operation, and Rieländer had a patient whose heart was irregular and weak more than a month after the employment of Momburg's method. Before Professor Gross and Dr. Binet's case only one fatal result had been recorded. This was in a patient under the care of de Bovis, and Momburg's method was employed for the arrest of internal hæmorrhage resulting from a hysterectomy for fibroma; the patient died half an hour after the tube was applied, but in this case it cannot be regarded as certain that the tube was the cause of the death, though de Bovis considered that death had been hastened by the tube. The case with a fatal issue observed by Professor Gross and Dr. Binet was one of amputation of the hip for tuberculosis of the knee. The patient was a woman 27 years old, and the extent of the disease was so great that Professor Gross advised amputation. The joint was completely disorganised, the tibia was displaced backwards and outwards, and a large abscess existed in the thigh. She was much wasted and had a septic temperature. The condition of the patient made it extremely important

that not a drop more blood should be lost than was necessary, and this fact suggested the employment of Momburg's method. Apart from her general health, there was no obvious contra-indication; she was young and her cardio-vascular system appeared to be healthy. The operation was performed on Feb. 11th, 1909. Chloroform was the anæsthetic employed. The patient was laid on her back and the legs were raised for ten minutes, and when the anæsthesia was complete, a rubber tube of about the size of the thumb was carried round the waist four times, and all pulsation in the femoral artery ceased. The radial pulse was unaffected except that its rapidity was increased to 110 beats a minute. The amputation was performed with an anterior flap, and no vessels bled. The wound was washed with peroxide of hydrogen applied very hot. Meanwhile the patient was breathing well and the pulse was normal. After the vessels had been tied, and while the skin stitches were being inserted the tube was slowly released, about a minute being occupied in this. At the very moment when the tube was completely removed the pulse suddenly stopped and the patient became pale. All attempts at resuscitation, including artificial respiration carried on for half an hour, failed. At the necropsy nothing abnormal was found in the aorta or vena cava. The right side of the heart was distended with blood and on the left side there were vegetations on the mitral and aortic valves, and there was some fatty degeneration of the heart. Professor Gross and Dr. Binet do not think that the chloroform was the cause of the syncope. It has been shown experimentally, in the application of Momburg's band, that there is a sudden and great increase in the work of the heart, and this they believe proved fatal. They advise that certain precautions should be taken in the employment of Momburg's method, and the most important of these is that the Trendelenburg position should be employed, so that the mesenteric vessels are not compressed by the tube, and thus much less increase of general blood pressure occurs. Secondly, the tube should be applied slowly and the pressure increased gently, and the same care should be taken as the tube is removed. Two or three minutes should be employed in the application and in the removal of the tube. We agree with Professor Gross and Dr. Binet that the fatal result in their case does not invalidate the great merits of Momburg's method, but it serves to emphasise the importance of extreme care in the employment of this method of hæmostasis.

ADVANCE IN ENGLISH VITAL STATISTICS.

AT a meeting of the Royal Statistical Society held on June 14th Dr. T. H. C. Stevenson, the successor of Dr. Farr, Dr. Ogle, and Dr. Tatham, as Superintendent of Statistics in the Registrar-General's department, read an interesting and valuable paper entitled "Suggested Lines of Advance in English Vital Statistics." The paper dealt with some of the more important changes contemplated in the statistics published by the Registrar-General in his official reports, which changes, it is proposed, should take effect in the new decennium which will commence with next year. Of these proposed changes, to some of which we may probably refer, by far the most important is one which has frequently been advocated in these columns—namely, the substitution, so far as may be possible, of administrative areas for registration districts. Those who recognise the increasing influence of mortality statistics on health progress will find it almost impossible to over-estimate the value and importance of adopting the administrative area as the unit for vital statistics. In its effect on the Registrar-General's statistics, the proposal to adopt a machine-sorted card system, with electrical tabulation by means of an improved Hollerith machine, comes second in importance. The paper draws attention to the fact that the substitution of administrative areas for registration districts will necessarily afford the means for comparison between the official statistics of the Registrar-General and those issued by local medical officers of health. The possible inconvenience arising from discrepancies between the official and local statistics appears to have been the subject of conference between the Local Government Board, the General Register Office, and the Association of Medical Officers of Health, and the paper suggests a somewhat elaborate arrangement for securing, so far as may be possible, uniformity in the distribution of deaths occurring outside the administrative area to which they belong, and in the classification of diseases. The practicability of some of these suggestions appears, however, to require most careful consideration. The paper naturally expresses regret that the most important of the suggestions contained in the report of the Census Committee of the Royal Statistical Society—namely, provision in the Census Act for an intermediate quinquennial census in 1916—has not been adopted by the Government on the ground of expense. Dr. Stevenson, however, anticipates that the additional information to be required in the Census schedule relating to the duration of marriage, and to the number of children of each marriage born, deceased, and surviving, will facilitate the construction of useful statistics bearing on so-called fertility, with a view to throw light upon the relative birth-rate in different grades of society, a subject of much interest to the students of eugenics. The reading of the paper was followed by a discussion in which appreciation of its interest and value was very generally expressed.

THE DIFFICULTY OF DIAGNOSIS BETWEEN SYPHILIS AND TUBERCULOSIS.

IN the recently published edition of his work on syphilis Sir Jonathan Hutchinson relates a typical case of recurring chancre on the end of the long prepuce of a man whom he had treated five years previously for syphilis with chancre in that position. The induration of the recurring chancre was extreme, and ulceration occurred at two points. When the patient came under observation mercury had been taken for a month without effect. Circumcision was performed and the specimen was sent to the Clinical Research Association in order that a search might be made for the spirochæta. To Sir Jonathan Hutchinson's surprise, Mr. J. H. Targett made the following report: "This specimen has the characteristic structure of a recent tuberculous infection. The surface exhibits a fissure-like ulcer beneath which there is a large area of young inflammatory growth. Scattered throughout this area are typical giant cells in great abundance. Many of them form 'systems' as in miliary tuberculosis and in the centre of the area there is a distinct focus of caseation. Though tubercle bacilli have not been found in these sections, there can be no doubt of the tuberculous nature of the lesion." Several skilled histologists who saw the section agreed with this conclusion. The wound healed well and the patient remained in good health. Sir Jonathan Hutchinson concludes that, in the absence of history, it is not possible to distinguish by the microscope between induration due to previous syphilis and induration due to tuberculosis, and quotes the statement of Dr. J. M. H. MacLeod: "The differentiation by the microscope between the granulomata of syphilis and tuberculosis is always difficult and in some cases impossible; for example, in the syphilitic gummata when a histological architecture may be present which resembles that of a lupus nodule in every detail with the exception of the presence of the tubercle bacilli." At a meeting of the

Société Médicale des Hôpitaux of Paris on March 11th M. J. Nicolas, M. M. Favre, and M. L. Charlet communicated an important paper on the Reactions of the Syphilitic to Tuberculin. They quoted a previous paper by M. Nicolas and M. Favre [1] in which it is shown that it is impossible to decide between syphilis and tuberculosis by histological examination of certain lesions of skin and mucous membrane. In 24 out of 25 cases of nodular secondary and tertiary syphilitic lesions there were found giant cells, epithelioid cells, and follicles in every respect identical with those of the most characteristic tuberculous lesions, so that even the most distinguished histologists when shown a series of sections, some of which were obtained from averred syphilitic lesions (proved so by the history, clinical characters, negative results of cultures and inoculation of guinea-pigs, and rapid recovery under mercury or iodide) and others from lesions proved to be tuberculous, failed to distinguish one from the other. In the present paper it is shown that the tuberculin tests also fail in the differential diagnosis. In 28 syphilitic persons, clinically free from tuberculosis, tuberculin was inoculated into the skin by von Pirquet's method. Twelve were in the secondary stage and gave the following results: 8 positive reactions, 2 feeble or doubtful reactions, and 2 negative reactions. Four were in the tertiary stage: 3 gave positive reactions, and 1 a feeble or doubtful reaction. Eleven were in the "quarternary stage" or had formerly suffered from syphilis but had no symptoms: 10 gave a positive reaction, and 1 a negative reaction. Further, the subcutaneous injection of tuberculin equally failed to distinguish between the two diseases. In a number of "clinically pure" syphilitic cases temperatures ranging as high as 103·8° F. and the other symptoms which are supposed to indicate tuberculosis were obtained. These results are explained by M. Fernand Arloing, who has shown that certain toxins—those of the typhoid bacillus, staphylococcus, and diphtheria bacillus, and particularly the syphilitic toxin—render the organism more sensitive to the effect of the tuberculin.

REVISION OF THE UNITED STATES PHARMACOPŒIA.

THE principles laid down for the guidance of the Committee of Revision of the United States Pharmacopœia at the Ninth Decennial Convention recently held at Washington do not differ materially from those followed by the committee responsible for the compilation of the last edition of that work. As to the scope of the Pharmacopœia the committee is authorised to admit any medicinal substance of known origin, but may not admit any substance or combination the composition or mode of manufacture of which is kept secret. Substances used only for technical purposes are not to be admitted, and a statement is to be placed in the preface to the effect that standards of purity and strength prescribed in the text of the Pharmacopœia are intended solely to apply to substances which are used for medicinal purposes and when professedly bought, sold, or dispensed as such. A useful innovation is to be the insertion, after each article used in prescriptions, of a carefully considered abbreviated name, which may be known as an official abbreviation, in order that uniformity may be established throughout the country. This is also intended to serve the purpose of preventing mistakes in reading prescriptions, and it is expected that pharmacists will label their bottles and other receptacles for drugs with these authorised abbreviated names. The committee is recommended to adopt the standards suggested by the International Conference for the Unification of Formulas for Potent Drugs, but they are not required to accept in detail the pharmaceutical processes recommended by that conference. So long as the finished product conforms to the international standard the Convention came to the conclusion that each country should be left free to adopt such details and methods of manipulation as might seem best. It is recommended that biological tests or assays should be admitted when accurate and reliable, but presumably the committee will only introduce such tests in connexion with drugs like strophanthus and digitalis, which cannot be assayed by chemical methods. Serums and other biological products of approved usefulness may be admitted in the next edition of the United States Pharmacopœia if standardised by a Government department. The introduction of new composite preparations is to be discouraged as far as possible. These recommendations are especially interesting in view of the fact that the British Pharmacopœia is also in process of revision, and no doubt the proper authorities in this country will take into consideration the plan of revision which it is proposed to follow in the United States. While the principles of pharmacopœia revision in the two countries are in many respects similar, the composition of the revising committee in the United States differs altogether from the responsible body in this country. In America the method of revising the work has been changed by the substitution of a committee of 50 and an executive committee of 15 for the former general committee of 26 members; 19 of the general committee of revision are teachers in colleges of pharmacy, 8 teachers in medical colleges, 8 retail pharmacists, 6 manufacturing chemists, 5 Government officials, 2 physicians in active practice, 1 chemist employed by the American Medical Association, and 1 wholesale druggist. The last edition of the United States Pharmacopœia became official in September, 1905, three months after publication. An interval of three months between the date of publication and the date on which the Pharmacopœia becomes official affords an opportunity for those engaged in the manufacture and sale of galenical preparations to meet the new requirements punctually. In this country the Pharmacopœia comes in force when a notice to the effect that it has been published has appeared in the London, Edinburgh, and Dublin *Gazettes* as provided by the Medical Act, 1862; and it may be remembered that notice of publication of the 1898 edition appeared a fortnight before the book was on sale.

THE SURGERY OF HEART WOUNDS.

Dr. C. H. Peck of New York City has recorded in the Transactions of the American Surgical Association for 1909 a case of wound of the right auricle. The patient was a coloured girl, 24 years old, who was stabbed in the chest with a pocket-knife about half an hour before her arrival at the hospital. No radial pulse could be felt, and the heart sounds could not be heard. The operation commenced about three-quarters of an hour after she received the injury. A square-shaped flap, with its base externally, was turned back; its upper margin was the second intercostal space and its lower the fifth space. The pleura was pushed outwards, and then it was seen that the wound in the pericardium was about half an inch in length and so close to the edge of the sternum that a portion of the bone had to be cut away with bone forceps. The intrapericardial tension was so great that no heart beats could be felt even by a finger on the sac. The pericardium was opened with a three-inch longitudinal incision one inch to the left of the stab and about 10 ounces of dark blood gushed out, and the return of the radial pulse was at once noticed. It was impossible to locate the wound in the heart until a transverse cut was made in the pericardium towards the right; then,

when the heart was lifted forward with the right hand and rotated slightly to the left, the wound in the right auricle three-quarters of an inch above the auriculo-ventricular groove was seen. It was nearly half an inch long and with each beat a stream of dark blood spurted out. A suture of Number 0 chromicized catgut was passed on a curved intestinal needle; the ends were left long at first in order to steady the heart, while three more similar sutures were inserted, and these completely controlled the hæmorrhage. An attempt was made to avoid piercing the endocardium with the stitches, but the movements of the heart were so rapid that the operator was not certain whether they entered the cavity of the heart or not. The pericardium was emptied of blood and clot by means of the hand and a gauze sponge, and it was closed without drainage. The flap was replaced and an intravenous saline infusion was given. The operation lasted just over an hour and recovery followed. For the first week there were signs of a mild pleurisy, but these cleared up by the end of the second week. The patient left her bed on the seventeenth day and was discharged from the hospital 34 days after the operation. Dr. Peck discusses the details of the operation, and he expresses himself as in favour of the square flap with the hinge externally. He gives a table of 159 cases classified according to the portion of the heart injured, and from this he shows that though most writers on heart wounds have considered wounds of the auricle to be more dangerous than those of the ventricle, yet the mortality of auricular wounds has been 36·3 per cent., while the general mortality of heart wounds is about 64 per cent. Dr. Peck's case shows the value of rapid operation in heart wounds. From the great intrapericardial tension it seems to be practically certain that cessation of the beating of the heart would have occurred before long had not surgical intervention taken place.

A NEW FORM OF HUMAN TRYPANOSOMIASIS.

IN the province of Minas Geraes, Brazil, a new form of human trypanosomiasis has been discovered by Dr. Carlo Chagas while engaged in organising anti-malarial measures for the protection of the labourers employed in constructing a new railway in that region. His attention was drawn to a large biting bug locally known as "barbeiro," which, infesting in large numbers the hovels of the poorer working class, remains hidden during the day time in the cracks of the walls or ceiling and issues forth at night when lights are extinguished to obtain its meal of blood from the occupants of the dwelling. This bug belongs to the Hemiptera heteroptera, family Reduvidæ, genus Conorrhinus; it is more than an inch in length and bites its human victim chiefly on the face. In the hind gut of this insect Chagas found numerous flagellates with the morphological characters of Crithidia. Some of these bugs were sent to Dr. Oswaldo Cruz, in whose laboratory they were allowed to bite monkeys, and 20 or 30 days later in the blood of these animals were found numerous trypanosomes differing obviously from other members of the genus. The parasite could also be transmitted to guinea-pigs, rabbits, and dogs, in whose peripheral blood the trypanosomes were constantly found, at times in increasing numbers. The new parasite has been named by Dr. Chagas Schizotrypanum cruzi. An abstract of the discoverer's original memoir has been recently published in the *Sixteenth Bulletin of the Sleeping Sickness Bureau*, to which we are indebted for the following particulars. Dr. Chagas made search for the usual host of this new parasite and for this purpose he examined the human occupants of some of the bug-infested hovels. In the blood of some of these persons he found the trypanosomes, as also in a domestic cat. In some of the houses he found children suffering from an illness characterised by extreme anæmia, with delayed development, œdema general or partial, enlargement of the peripheral glands and spleen, and functional disturbances, especially of the nervous system, with frequent occurrence of actual imbecility. No mention, however, is made of somnolence as a symptom; in this particular the South American trypanosomiasis appears to differ from the African variety. The mortality among the children attacked seems to be great, the deaths being often attributed to "convulsions." The local names of this malady—"opilaçao" or "canguary"—are the same as are given to ankylostomiasis, which in many respects it resembles; but Dr. Chagas excluded the latter disease from his cases by careful examination of the patients' fæces. It is admitted that the course of this new disease is as yet only imperfectly known, and therefore more study of its clinical characters and progress is needed. From the blood of the patients experimental animals could be infected in the laboratory, and the parasites could also be cultivated on artificial media outside the animal body. It is not contended that all the bugs in the hovels become infected, nor that all the bugs having flagellates in their hind gut can convey the disease to vertebrates. In a few instances the trypanosomes were found in the salivary glands of the insects, and it is therefore suggested that possibly only those bugs presenting this condition are capable of transmitting the disease. Dr. Chagas sums up the results of his laboratory investigations as follows: Schizotrypanum cruzi has in the organism of the Conorrhinus two methods of development—the first representing a simple culture of the parasite; the second, probably ushered in by sexual processes not yet observed, showing perhaps the cycle of development which occurs in the transmission from vertebrate to vertebrate. Conorrhinus is the true intermediate host of Schizotrypanum cruzi, the development cycle of which occupies a period of at least eight days. The flagellates of Crithidia type, which occur in the free living Conorrhinus, may be culture stages of the Schizotrypanum or exclusively insect parasites. The occurrence of the sexual cycle of development in the organism of Conorrhinus depends on states of the flagellates, in the blood of the vertebrates, as yet unelucidated.

CHRONIC DIFFUSE PARENCHYMATOUS NEPHRITIS.

THE Address in Medicine delivered at the annual meeting of the Canadian Medical Association by Dr. W. P. Herringham (the proceedings of which are re-reported at p. 1787) was devoted to a practical clinical study of chronic diffuse parenchymatous nephritis, based upon his own experience of cases of this condition. The morbid anatomy of this form of nephritis has been carefully studied by numerous observers, and it is generally recognised that various forms exist. In some fatty changes predominate, leading to the condition of "large white kidney," while in others fibrous lesions are marked, leading to a "small white kidney," but perhaps the most common form is one in which both forms of change co-exist, constituting the fibro-fatty kidney. The pathology of these conditions is still obscure, since it is difficult to determine the part played by infection in their production, and the relation of the various forms to one another is still the subject of controversy. Some authorities affirm that the small white kidney is a later stage of the large white, while others, and among them Dr. Herringham,[1] consider that there is no evidence of this. One of the special dangers of an attack of nephritis to which Dr. Herringham paid special attention in his address is the vulnerability of the kidneys which it leaves behind as a sequel, rendering them especially liable

[1] Text-book of Medical Practice. Edited by William Bain. London, 1904, p. 443.

to recurrence of the nephritis. He likened a patient with chronic Bright's disease to a town of which the drainage was out of order. The diet in nephritis has been the subject of so much discussion on theoretical and experimental grounds that a statement of the results of clinical experience is of special value. Dr. Herringham, while urging the importance of diet in the treatment of the disease, maintained that moderation in regard to quantity was of much greater importance than the elimination of certain articles from the diet list. He recommended ordinary diet, and did not restrict his patients to fish and certain special foods, but allowed them to partake of meat. In this he is in accord with the recommendations of von Noorden. There can be little doubt that undue and prolonged restriction of the dietary of patients with chronic parenchymatous nephritis is not beneficial and tends to aggravate the anæmia from which the patients are liable to suffer. In regard to treatment Dr. Herringham stated that the main object was to avoid the condition of uræmia by maintaining a fair excretion of urine. The treatment of hæmaturia and of œdema must often prove a difficult task. We shall await the full text of Dr. Herringham's address with interest, for from the *résumé* we have received it was obviously an interesting practical contribution to the study of this complex disease.

OVARIAN DERMOIDS AND THE RESULTS OF THEIR RUPTURE.

THE after-histories of cases in which cysts have ruptured into the peritoneum are always interesting. In the case of dermoid cysts the result would appear to depend generally upon whether there has been a leakage of the contents of the cyst or actual rupture with the escape of all or the greater portion of the contents into the peritoneal cavity. A most interesting case of the latter kind is recorded in this issue of THE LANCET by Mr. R. H. Lucy. In a single woman, 32 years of age, in whom the abdomen was distinctly distended and pitted on palpation, a diagnosis of a dermoid cyst was made. On opening the abdomen it was found that the cyst had ruptured and that the peritoneum was full of pultaceous material, of which some 11 pounds were scooped out. A large dermoid cyst, apparently of the right ovary, was removed, and probably also one of the left ovary, while a secondary implantation cyst was present attached to the parietal peritoneum, which presented a patch some 2½ inches in diameter, covered with black hair. The abdomen was drained and the patient made a good recovery. The leakage of the tumour had probably existed for some 19 months before her admission to the hospital, although she herself was positive that the curious pitting of the abdomen had existed since puberty. As Mr. Lucy says, this case presents a most remarkable instance of the tolerance shown by a serous membrane to the presence of material foreign to its normal secretion. In a very interesting paper read before the Obstetrical Section of the Royal Society of Medicine Mr. T. W. P. Lawrence and Dr. Martin Randall[1] recorded a case in which a puncture was made into an abdominal swelling which at the time, owing to the condition of the patient, it was impossible to remove. At a second operation, when the cyst was removed, several secondary cysts were found attached to, and growing in, the omentum. As the writers point out, when a dermoid cyst leaks a number of epithelial cells become scattered over the surface of the peritoneum, and from these cells small cysts develop. The second class of case, of which Mr. Lucy's is an instance, includes cases of large cysts which have burst and the contents have escaped into the peritoneal cavity. A very good example of this kind is that recorded by Fraenkel, in which in a woman 37 years of age, nine months after a fall from a cart, the abdomen was opened for an abdominal tumour, and no less than five litres of yellowish green fluid, containing fat, sebum, cholesterin, and epithelium, which had escaped from a ruptured dermoid cyst, were found in the peritoneum. Unfortunately, in this case the patient died from suppurative peritonitis. Of these most interesting cases eight were collected by Mr. Lawrence and Dr. Randall, and in the discussion Dr. A. L. Galabin recorded a similar case, making with the present case a total of ten. Practically in all, except in Fraenkel's patient already mentioned, the rupture occurred spontaneously, and there was no history of any injury indicating the time of the rupture, while in all the cases except that of Kolaczk the primary tumour was densely adherent. A most instructive case is that of Grawitz, in which at a necropsy a number of secondary implantation tumours were found in the abdomen, their walls consisting of fibrillated connective tissue, and so differing in structure from true dermoids. Mr. Lucy is to be congratulated on the successful result of his case, for in no less than five of seven of those operated upon a fatal result followed the operation. No doubt the case is one, as he says, of epithelial infection so-called, and not an example of a malignant embryoma.

A SPECIAL matinée on behalf of the National League for Physical Education and Improvement, will be held at St. James's Theatre, by kind permission of Mr. George Alexander, on Friday, July 1st, at 2.15 P.M. A number of distinguished actors and actresses have kindly promised to take part in the theatrical performances, and there will be a display of physical drill by the students of Mme. Bergman Österberg's College. Tickets may be obtained from the Secretary, National League for Physical Education and Improvement, 4, Tavistock-square, London, W.C., and the Box Office, St. James's Theatre, King-street, S.W.

THE Cavendish lecture will be delivered before the West London Medico-Chirurgical Society by Sir Thomas Oliver on Friday, July 1st, at 8.15 P.M., in the Town Hall, Kensington. The subject selected is, "Empyema and Some Problems Connected Therewith."

COLONIAL MEDICAL SERVICES.—*West African Medical Staff.*—Mr. H. Carlaw retires with gratuity. Dr. P. J. Kelly, medical officer, Gold Coast, has been transferred to Hong-Kong. The following promotions have been notified: Dr. M. C. Blair, senior medical officer, Northern Nigeria, to be Senior Sanitary Officer, Northern Nigeria; Dr. R. H. Kennan, senior medical officer, Sierra Leone, to be Senior Sanitary Officer for Sierra Leone and the Gambia; Mr. W. F. Macfarlane, medical officer, Southern Nigeria, to be Senior Medical Officer, Southern Nigeria; and Mr. C. E. S. Watson, medical officer, Northern Nigeria, to be senior medical officer, Northern Nigeria. The retirement of Mr. T. R. Frazer Toovey, medical officer, Southern Nigeria, has been cancelled. The following gentlemen have been appointed to the staff: Dr. J. A. Beamish (Gold Coast), Mr. C. W. S. Boggs (Gold Coast), Mr. D. T. H. Croly (Gold Coast), Dr. D. Duff (Gold Coast), Dr. M. W. Fraser (Gold Coast), Mr. G. H. Gallagher (Southern Nigeria), Dr. S. Goodbrand (Gold Coast), Mr. J. E. Moffatt (Gold Coast), Mr. R. Mugliston (Gold Coast), Dr. W. A. Nicholson (Sierra Leone), and Dr. J. Y. Wood (Sierra Leone).—*Other Colonies and Protectorates:*—Mr. P. Harper has been appointed a medical officer in Fiji; Mr. W. R. W. James, medical officer in Uganda, has been appointed a medical officer in Ngamiland, Bechuanaland Protectorate; and Dr. J. C. McPherson has been appointed a supernumerary medical officer in the Leeward Islands.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The Life of a Car.

THERE comes to all of us, I presume, a time when we would gladly get out of the groove in which we are existing. In medical matters this is not always an easy performance Even in automobile affairs the groove is often stronger than the man. There are so many arguments in favour of one's old car. We know its faults and its limitations; it is an old friend. Why not spend a few pounds, rebush the engine and gearbox, put in, perhaps, a new gear, maybe fresh thrust bearings, and go on, especially as old cars are difficult to dispose of? This brings me to the query at the head of this paragraph, What is the useful life of a car? Frequently have I been asked, How many miles can a car run before it is done for? It is impossible to reply. I believe that if an owner took care to keep his machine in repair, tuned up, the nuts always tight, and bearings oiled, it would, like Tennyson's brook, "run for ever." Owners might come and might go, but a good old car will clatter on for ever. I have at different times haunted motor auction-rooms and seen many a scrap-heap relic which with an expenditure might have had a new life and many possibilities, including, of course, educational ones. But there's the rub—there may be break-downs and it may cost more to keep an old car in repair than to run it.

Recently I had the pleasure of a "petrol chat" with a Cornish colleague. He began his automobile experiences with one of those inventions on three wheels which carried the engine in the front wheel. In point of time this was not so long ago, but as the development of the car goes it seems a distant age. What with capsizing in rounding corners, falls from colliding with dogs, the exhaustive pedalling needed to get the engine to fire on a gradient and ascend a hill, and when to all these disabilities was added a noise like that of Gatling guns, it is astonishing what pleasure the owner derived. This machine, for which he paid £80, eventually became the property of a clergyman for the sum of £5, and is, I believe, still running.

My friend's next venture was a 5½ h.p. American production, with one merit—it was remarkably silent. It also frequently demonstrated the difference between the pride of the run out and the humiliation of the walk home. It had a clutch which would slip, a cooling system in which the air would cause a lock, and finally, when the cylinder cracked, it was given in part payment for a two-cylinder Wolseley. This was second-hand, but with it the medical owner could finish his morning round an hour earlier than with a horse, and it also dispelled the terrors of late messages. I understand that this car covered in 18 months 10,000 miles. Excluding the driver's wages the cost for running was £268 10*s.*, and the details of expenditure are as follows:—

	£	*s.*	*d.*
Tyres, including a vulcaniser	93	11	1
Repairs and replacements	88	12	6
Petrol and accumulator charging	45	7	6
New horn	2	5	0
Insurance (two years)	20	0	0
Chauffeur's insurance	1	10	0
Coach builder (twice touching up and varnishing car)	12	10	0
Licences (two years)	4	14	0
Total	268	10	1

With the present petrol tax there would have been an increase of £7 in the amount. Personally, I think such a small car could have been run for much less, and I certainly do not put these figures forward as a standard of what the cost should be, but I mention them as a statement of actual facts, given by a most careful colleague, who has kept accurate notes. They show what a car may cost, practically in this case a fraction over 6*d.* per mile, without taking into account the question of depreciation. I consider the old Wolseley cars as reliable as any that have been or probably will be built; and though the owner may have been unlucky, his case shows that though an old car can be got to run, and, what is more, run well, it does not always pay to do so. Against this, perhaps, I ought to give my own contrary results, as I still have, and often use, an eight-year-old single-cylinder Wolseley, which I run for about three days every week at a cost of £40 a year, but I do not claim any art or subtlety for this, it is luck. Anyway, my friend came to the conclusion that it was cheaper to practically give away his car and indulge in a new one; perhaps he is correct.

The Question of "New Cars for Old."

Occasionally some slight defect develops in a car. Perhaps a cylinder oozes a little—that is, the casting, even though after machining it has passed a pressure test, has in some spot a small minute pin-hole, or is porous. Probably there was a faint skin over the porous part or pin-hole; thus the casting got through the test, searching though it may have been. The car had good pressure on its trial run, but after a little work the skin wore, and perhaps compression in one cylinder became poor, or a little water entered the cylinder. The owner wisely takes his car to the makers and new cylinders are supplied and fitted free of charge. While there the motorist, having the "motor fever," sees some later type, and the makers, partly out of desire to compensate and partly to do some more business, suggest an exchange. They offer a new machine quite up to date for the old one *plus* a little cash. Perhaps the original automobile was a two-cylinder, with a two-seated body; a four-cylinder is suggested with a side-entrance body. A quotation of Dryden is perhaps appropriate:—

> "Trust in, and think to-morrow will repay;
> To-morrow's falser than the former day;
> Lies worse, and while it says we shall be blest
> With some new joys, cuts off what we possest."

The old car is now as good as new; in fact, it is better, for it has been tested, and the only defective piece has been removed and replaced by a new one; therefore, why change? The original car is excellent for the work wanted of it; it is of sufficient horse-power. The newer one is of a higher power, and thus a heavier tax would have to be paid on it; it is also heavier, and so would be more expensive in the matter of petrol and tyres. It would therefore seem as well in such cases to try to conquer the "motor fever" and not to discard a good servant and ever be seeking some new thing, even though it tempt the heart and allure the eye.

On the Choice of a Second Car.

This is often a more difficult question to decide on than even the original choice. The first mount is old, and has probably been a good servant for years. It is ancient, but still answers its purpose. Among the drawbacks it possesses, however, is that of rattling. Of course, adjustment of brake-connecting rods, rebushing of parts that have worn, and fitting new bolts that do fit, as well as, perhaps, altering the cam shaft so that the valve's descent is gradual before it strikes its seat, and may be a more modern silencer, would do away with much of the rattle. Still, other colleagues have more silent and more up-to-date automobiles and accordingly the car is condemned. Then the question arises, Shall the old make be adhered to, or shall the product of another firm be tried? This is a difficult matter to settle. If the original manufacturers are still in business and turning out, as nearly all are, up-to-date modern machines, and if they have always been obliging and ready to meet the owner in the matter of repairs and replacements, then, especially if they will make an allowance for the old car, there seems much in favour of at any rate entering into negotiations with the makers of the first car.

The Hardre Safety Lighter.

Those who, when visiting at night-time, have attempted to light their acetylene lamps in the open have probably wasted time and matches. Consequently this little self-lighting device will be welcome; although not a complicated appliance it is a very efficient one, as I have found from actual experience. It is small enough to be carried without inconvenience, is safe, is always ready for use, and will give over 6000 flashes; the price is 6½*d.* It can be obtained from most dealers, but in case of difficulty can be had direct from Messrs. Brown Brothers, Limited, of Great Eastern-street, London, E.C.

THE REGISTRAR-GENERAL'S ANNUAL SUMMARY FOR 1909.

IN THE LANCET of May 28th we acknowledged receipt of the above-named publication, which had been issued a few days previously by H.M. Stationery Office. Like its predecessors of recent years, the Annual Summary for 1909 is compiled from the weekly and quarterly returns of the local registrars for London and for the chief provincial cities and towns of England and Wales. In this summary the name of Mr. Bernard Mallet appears for the first time as Registrar-General.

Need of a Quinquennial Census.

Following the example of his predecessor, Mr. Mallet rightly emphasises the need of a quinquennial census for the estimation of local populations, and he points out that in its absence most of the rates of marriages, births, and deaths that are now in course of publication may require serious modification when the results of the forthcoming enumeration are accessible. Whatever methods are employed for the tabulation of the facts of registration the rates corresponding to those facts must be regarded as merely provisional and often as of doubtful accuracy, especially as the end of a decennial period approaches. The disadvantage of an unduly protracted intercensal period affects the work of the General Register Office even more seriously than it does that of the local administrative authorities, and in present circumstances the difficulty of framing local population estimates at the central office is increased by the circumstance that any method adopted there must be applicable to all districts alike, because no cognisance can be taken of local sources of information. On the other hand, local authorities are frequently able to frame more reliable estimates than those of Somerset House, because of their possessing information collected from the local rate-books and other official sources which may throw light on the movements of population from year to year.

Question of Assimilating the Areas of Registration and Administration.

In a leading article in our issue of Jan. 1st on the Registrar-General's annual report for 1908 we commented on the question of assimilating the areas of registration and administration for the presentation of mortality statistics, with especial reference to the difficulties inseparable from that process. Ever since the creation of special areas for sanitary purposes, proposals have been made from time to time that the registration areas should, as far as possible, be made coterminous with the administrative areas—a change which, if the technical difficulties could be overcome, would undoubtedly increase the practical value of the vital statistics of the Registrar-General by bringing them into touch with the local administration of the country. Mr. Mallet agrees with Sir William Dunbar in the opinion that in order to give effect to this proposal nothing less than a new Registration Act would be required; but he thinks that, short of such legislation, it may be practicable to redistribute the returns according to administrative areas, although for the present the facts must be collected on the old registration lines. Nevertheless, there still remains unsolved the fundamental difficulty of securing that the methods of classification employed by the local medical officers of health should be identical with those of the central office; and having regard to the importance of the personal equation in such matters we are inclined to repeat the suggestion already offered in these columns that the local statistics of birth and mortality for at any rate the larger administrative areas of England and Wales should be prepared at Somerset House and issued periodically to the local authorities concerned. By this method the grave disadvantages attaching to the publication of national and local statistics relating to the same areas but compiled by different methods, and therefore presenting avoidable discrepancies, would be avoided.

Correction of Mortality-rates in Summary for Age-constitution, &c.

As in recent previous years, the mortality-rates in the present summary relating to the administrative areas of London and of the extra-metropolitan cities and towns have been approximately corrected for institution deaths and for varying age differences of the living; they may therefore be accepted as the best practicable at this great distance from the census. But the present figures for England and Wales as a whole and its registration divisions must be regarded as merely provisional; a more detailed analysis of the figures derived from the national registers being now in progress, the results of which will appear in the Registrar-General's annual report for 1909, which will be published later in the year.

Prospective Changes.

Reverting to the subject of prospective changes in the annual summary, the Registrar General tells us that after the year 1911, when the changes now in contemplation will come into operation, the whole of the figures for England and Wales and portions thereof now published in the annual summary will revert to the character of an estimate. The issue of an annual summary will still be continued because the information it contains can be published from six to nine months earlier than that contained in the annual report, but its importance will be greatly diminished, and it may be found advisable to reserve for the annual report some of the figures now given in the summary in cases where early publication is not of sufficient importance to justify the issue of information of a provisional nature. But if by the foregoing intimation it is to be understood that in future the rates of mortality concerning the chief English towns are to appear in the annual summary without correction either for institution deaths or for variations in age-constitutions of the population, we cannot avoid the conclusion that the change foreshadowed is a retrograde one, and we hope that in this matter the Registrar-General may reconsider his decision before the time arrives for the preparation of the annual summary for 1911.

The Decline in the Birth-rate.

In England and Wales generally the rates of marriages, births, and deaths in the year 1909 were severally below the average, the death-rate at all ages, as well as the infantile death-rate, being lower than in any other year on record. Calculated, for convenience, in terms of persons living of both sexes, the rate of births last year showed a decrease of 2·2 per 1000 as compared with that of the ten-year period 1899–1908. As in previous years, the proportions varied considerably in the several registration areas; for whilst it did not exceed 21 per 1000 in the agricultural counties of Dorset, Somerset, and Cornwall, it amounted to 33 per 1000 in the county of Durham, 35 in Glamorgan, and 36 in Monmouth. In the 76 principal towns, each of which contained at the last census more than 50,000 inhabitants, the birth-rates showed even greater variation, the rates in Hastings and in Hornsey being only 15 per 1000, whilst they rose to 34 in Tynemouth, 36 in Merthyr Tydfil, and 41 in Rhondda. In the 143 smaller towns, each of which at the last census contained from 20,000 to 50,000 inhabitants, the variation was even greater still, the rate being as low as 14 per 1000 in Margate, whilst it exceeded 44 per 1000 in Ebbw Vale.

In this summary the Registrar-General directs attention to the general decline in the birth-rate of the principal cities of the world, a decline which varies greatly in the different cities. If the birth-rates in the chief European cities in 1881–85 be compared with those in 1901–05, it will be seen that no appreciable change took place in Dublin, Belfast, or St. Petersburg; in the cities of Paris and The Hague, on the other hand, the fall amounted to 26 per cent., in Hamburg to 27 per cent., in Stockholm to 28 per cent., in Turin to 29 per cent., in Berlin to 30 per cent., in Prague to 32 per cent., and in Brussels to as much as 36 per cent.

Throughout the administrative County of London stillbirths are now recorded under the Notification of Births Act. From figures supplied by the county medical officer of health it appears that out of 61,884 notified births reported last year 1407, or 2·3 per cent., were stillbirths. For Metropolitan boroughs the proportions vary greatly, ranging from 1·1 per cent. to 3·6 per cent. of the total births certified in the several boroughs.

Death-rates.

Considerable variation was also observed in the death-rates of the several English and Welsh counties; for whilst the rate did not exceed 12 per 1000 of the population in Middlesex, in Essex, or in Kent, it ranged upwards to 16·1 per 1000 in the North Riding of York, to 16·5 in Carmarthen, and to 16·6 in Lancaster. Compared with

the death-rate of the preceding year, the fall in 1909 is due to diminished mortality among infants below the age of one year, which more than counterbalances the slight increase recorded in the mortality at the opposite extreme of life. In the administrative areas of the principal towns the mortality varied enormously, for whilst the crude rate did not exceed 8·3 per 1000 in Hornsey or in Erith, it amounted to 20·2 per 1000 in Longton, 21·1 in Makerfield, and 22·2 in Tunstall. Infantile mortality was low throughout the year under notice, the rate averaging 109 per 1000 births and being below the rate in the previous decennium by 29 per 1000. Previous to 1905 the lowest infantile mortality reached in England was 130 per 1000, in the year 1881, the cold wet summer of which year resembled that of 1909; a return of hot summers may lead to an increase in infantile mortality. In 1909 the loss of infant life was relatively greatest in the more populous counties; thus it was equal to 130 per 1000 births in Lancashire and 131 in Stafford, whilst in the rural counties of Hertford, Buckingham, and Wilts it did not exceed 74 per 1000. Among the principal towns infantile mortality was highest in Wigan (173 per 1000), in Swansea (159), and in Middlesbrough (158); it was lowest in Guildford (55 per 1000) and in Hornsey (61). From the list of towns with high infantile death-rates it appears that the inhabitants of most of these towns are mainly employed in the mining, textile, and pottery industries, and the rates indicate that these occupations are frequently associated with conditions inimical to infant life.

Infectious Diseases.

Among the common infectious diseases measles alone showed increased mortality in 1909, as compared with recent previous years, all other diseases of this class being less fatal than usual. By request of the Local Government Board the Registrar-General now publishes periodical returns of cases of certain infectious disease notified to the sanitary authorities of London and of several of the large provincial towns. Of the common infectious diseases the only ones not generally notifiable under the Act are measles, whooping-cough, and diarrhœa. Compared with the previous five years scarlet fever was the only notifiable disease showing unusual prevalence, in the year under notice, in the 76 great towns taken as a whole; and, compared with the same standard, the only diseases showing unusual prevalence in the aggregate in the 143 smaller towns were scarlet fever and diphtheria. Small-pox was reported last year in 15 of the chief English towns. Of the cases then reported 35 were in Bristol, 21 in London, 6 in Hull, and 5 each in Liverpool and Bolton. From scarlet fever the case rates ranged from less than 1 per 1000 of the population in Ilkeston, Jarrow, Middleton, and Bath, to 12 per 1000 in Glossop and in Shrewsbury and 23 per 1000 in Chester and in Ebbw Vale. For diphtheria the lowest rate (0·1 per 1000) was experienced in Llanelly and in Glossop; the highest rates were 5·0 in Derby, 5·2 in Eastbourne, and 7·2 in Lincoln. Enteric fever showed less prevalence than usual in the year under notice throughout England and Wales. In London both the reported cases and the admissions to the Metropolitan Asylums Board Hospitals were considerably fewer than the average. In the 76 great towns the enteric fever case-rate varied from 0·04 per 1000 in Hornsey and in Hastings to 1·27 in Portsmouth and 1·98 in Grimsby.

Tuberculosis.

The Registrar-General does not as yet publish separate particulars of mortality from tuberculous phthisis for the provincial towns, but from a table in the present summary it appears that in the metropolis the mortality last year from this disease corresponded to a rate of 1·31 per 1000, which is below the average rate in the previous five years by 0·13 per 1000.

Two important tables are here published for the first time. They show for each metropolitan borough the number of deaths from this disease of persons of each sex and of several ages occurring in institutions and in private houses. The chief interest of these tables is in regard to the question of the extent to which patients in the later stages of phthisis are prevented by segregation in institutions from spreading the disease among the general community. The proportion of institution deaths is shown to be greater in those boroughs where the conditions of life render most difficult the control of infection when patients remain at home. The phthisis death-rate is also highest in the same boroughs; but it may fairly be contended that in these districts the conditions favour the spread of infection to such an extent that without segregation the death-rate would probably be higher still.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 23rd, 1832.

IF the causes of the epidemic cholera have given rise to multifarious speculations, and if its pathological characters have perplexed all the reformers of nomenclature, the treatment proposed for the cure of this terrible malady has not been less the theme of controversy, and a profitable source of trade to impudent quacks, and other unprincipled pretenders to a knowledge in the science of medicine.

Did we credit a tithe of the assertions ostentatiously put forward, with all the impress of time and place, of the asserted success of a thousand alleged remedies, our wonder would be that the cholera has not long since been spirited off to the Red Sea, or some such hospitable asylum for banished humbug. Not a journal, medical, religious, political, or literary, is printed for circulation without containing a cure, a "certain cure" for the cholera, with statistical tables of the results, specifying when and where, names, dates, &c., &c., in a rank and file accuracy well calculated to carry home irresistible conviction to the uninformed mind. As this point is of some importance to be proved, we may appeal for our evidence to the history of the disease, from its irruption in Jessore to its present state in London. We find that in Bengal the moxa worked such wonders that scarcely a patient died on whom it was fairly tried. The drogue ancere was equally fortunate in Bombay. Acupuncturation saved every one in Japan. A combination of calomel and opium was a specific in Calcutta. In Persia, cold water did all that was required. In Cronstadt the actual cautery again became ascendant. At Constantinople, out of 200 patients, Dr. M'Guffog cured 196 by mere venesection. We know not in how many places burnt cork, given in milk, at once dispelled the disorder; and our journal would hardly contain the names alone of those districts where "pure brandy" was a never-failing panacea. What inference can we derive from the contemplation of these varied statements? Either the disease is more contemptible than a colic, or else the narrators have exaggerated the circumstances of their pretended successes; for that one and the same malady could be amenable to such a multitude of dissimilar specifics, is contrary to the evidence of general pathology and of common sense.

That the cholera is the harmless bugbear which one branch of our inference would make it, we cannot, unfortunately, admit, while we recollect the scenes witnessed in this metropolis, and while we bear in mind the melancholy statistical facts collected during its progress over Asia and Europe. We are consequently left to the disagreeable alternative of confessing that the truth has not been rigidly adhered to in the reports which have been issued during the progress of the terrible epidemic. Under such circumstances it is manifest, that, for the future, the merits of any novel method of treatment of cholera will be canvassed by the medical profession in a spirit of the most severe and cautious inquiry. The most scrutinizing scepticism will prevail, and no fact will be admitted until demonstrated by evidence of a perfectly incontrovertible description.

Dr. Arnold Chaplin has been appointed medical officer in London to the Standard Life Assurance Company, in succession to Dr. James Johnston, retired.

NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.—The twenty-sixth report of this society shows that 250 trained inspectors have been engaged in the work of the society during the year ending March, 1909. Over 50,000 cases of cruelty and neglect have been dealt with, neglect and starvation heading the list with the number 45,000. There is an increase in the total number of cases over the previous year of 2878, or about 50 more per week. The address of the society is 40, Leicester-square, London, W.C.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8613 births and 3591 deaths were registered during the week ending June 18th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 13·8 to 11·4 per 1000, further fell to 11·1 in the week under notice, and was considerably lower than in any previous week of this year. During the first 11 weeks of the current quarter the annual death-rate in these towns averaged only 13·0 per 1000, and in London during the same period it was so low as 12·5. The lowest recorded annual rates of mortality during last week in these 77 towns were 4·4 in Willesden, 4·9 in Southampton and in Grimsby, and 5·8 in Handsworth; the rates in the other of the 77 towns ranged upwards, however, to 16·9 in Stockport, 17·0 in Merthyr Tydfil, 19·6 in Newport (Mon.), and 20·1 in Swansea. In London the recorded death-rate last week was so low as 10·6 per 1000. The 3591 deaths registered last week in the 77 towns showed a further decline of 128 from the low numbers in recent weeks, and included 356 which were referred to the principal epidemic diseases, against 425, 369, and 381 in the three preceding weeks; of these 356 deaths, 113 resulted from whooping-cough, 106 from measles, 75 from diarrhœa, 30 from diphtheria, 22 from scarlet fever, and 10 from "fever," but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·1 per 1000, against 1·3, 1·1, and 1·2 in the three preceding weeks. No death from any of these epidemic diseases was registered last week in Brighton, Southampton, Norwich, Preston, Burnley, or in 11 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·6 in Newport (Mon.), 3·1 in Liverpool, 3·5 in Gateshead, and 3·9 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had been 159, 122, and 120 in the three preceding weeks, further declined to 113 last week, but caused annual death-rates equal to 1·5 in Stockport and in Bootle, 2·0 in Gateshead, and 2·6 in Newport (Mon.). The 106 deaths from measles showed a decline of 43 from the number in the previous week, but caused rates equal to 1·2 in Bradford, 1·4 in Liverpool, 1·6 in Barrow-in-Furness, and 2·0 in Merthyr Tydfil. The deaths attributed to diarrhœa, which had not exceeded 46 and 49 in the two previous weeks, rose under the influence of summer temperature last week to 75; this disease was proportionally most fatal in Gateshead. The 30 deaths referred to diphtheria showed a slight increase upon recent weekly numbers, and included 11 in London and its suburban districts, 3 in Salford, and 2 in Middlesbrough. Of the 22 fatal cases of scarlet fever, exceeding the number in the previous week by 2, 3 occurred in Liverpool and 2 both in Manchester and in Sheffield. Only 10 deaths in the 77 towns during the week were referred to enteric fever. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital further declined last week to 1363, and were fewer than at any time during the last six months; 166 new cases of this disease were admitted to these hospitals during last week, against 203 and 181 in the two preceding weeks. Of the 993 deaths registered in London during last week only 94 were referred to pneumonia and other diseases of the respiratory system, and were 58 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 25, or 0·7 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in London, Leeds, Sheffield, Bristol, West Ham, Bradford, Hull, Stoke-on-Trent, Leicester, and in 50 other smaller towns; the 25 uncertified causes of death in the 77 towns last week included 3 in Birmingham, 3 in Nottingham, 3 in Blackburn, and 2 each in Liverpool and in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 920 births and 503 deaths were registered during the week ending June 18th. The annual rate of mortality in these towns, which had been equal to 14·3 and 14·2 per 1000 in the two preceding weeks, further declined to 13·9 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 15·7 per 1000, and exceeded by 2·7 the mean rate during the same period in the 77 largest English towns. The annual death-rates last week in these eight Scotch towns ranged from 10·4 and 12·4 in Edinburgh and Aberdeen, to 20·5 in Dundee and 20·6 in Greenock. The 503 deaths from all causes in the eight towns during last week showed a further decline of 11 from the numbers in recent weeks, and included 42 which were referred to the principal epidemic diseases, against 50 and 59 in the two preceding weeks; of these 42 deaths, 15 resulted from measles, 15 from diarrhœa, 6 from whooping-cough, 3 from diphtheria, 2 from scarlet fever, and 1 from "fever," but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·2 per 1000, against 1·1 in the 77 English towns; the highest rate from these diseases in the Scotch towns was 2·8 both in Dundee and in Paisley. The fatal cases of measles in the eight towns, which had declined from 52 to 13 in the six preceding weeks, were 15 last week, of which 5 occurred both in Glasgow and Dundee and 4 in Paisley. The 15 deaths attributed to diarrhœa showed a decline of 7 from the number in the previous week, and included 6 in Glasgow, 3 in Dundee and 2 both in Aberdeen and Greenock. The 6 fatal cases of whooping-cough were fewer by 3 than those in the previous week; 5 were returned in Glasgow. The 2 deaths from scarlet fever occurred in Glasgow; and the fatal case of "fever" was recorded in Greenock. The deaths referred to diseases of the respiratory system in the eight towns, which had been 82 and 67 in the two preceding weeks, further declined to 56 in the week under notice, and were 17 below the number in the corresponding week of last year. The causes of 10, or 2·0 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 702 births and 418 deaths were registered during the week ending June 18th. The mean annual rate of mortality in these towns, which had been equal to 21·1, 18·0, and 17·8 per 1000 in the three preceding weeks, rose again to 18·9 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these Irish towns averaged 20·7 per 1000, whereas the mean rate during the same period did not exceed 13·0 in the 77 largest English towns and 15·7 in the eight principal Scotch towns. The annual death-rate during last week was equal to 17·1 in Dublin, 24·4 in Belfast, 15·1 in Cork, 10·8 in Londonderry, 20·5 in Limerick, and 15·6 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 15·2 per 1000. The 418 deaths from all causes in the 22 town districts last week showed an increase of 25 upon the number in the previous week, and included 68 which were referred to the principal epidemic diseases, against 58 and 55 in the two preceding weeks; these 68 deaths in the Irish towns were equal to an annual rate of 3·1 per 1000, while in Belfast it was so high as 7·9; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·1, and in the eight Scotch towns 1·2 per 1000. The 68 deaths from these epidemic diseases in the Irish towns last week included 52 from measles, 7 from whooping-cough, 6 from diarrhœa, 2 from diphtheria, and 1 from enteric fever, but not one from scarlet fever or from small-pox. The fatal cases of measles in the 22 towns, which had been 33, 39, and 40 in the three preceding weeks, further rose to 52 last week, of which 49 occurred in Belfast, 2 in Londonderry, and 1 in Dublin. Of the 7 deaths from whooping-cough, 4 were returned in Belfast and 2 in Dublin; and the 6 deaths attributed to diarrhœa included 4 in Belfast. Both the fatal cases of diphtheria occurred in Belfast; and the death from enteric fever was returned in Dublin. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 90, 75, and 78 in the three preceding weeks, declined to 62 last week. The causes of 15, or 3·6 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

death last week did not exceed 0·7 per cent., and in the eight principal Scotch towns 2·0 per cent.

VITAL STATISTICS OF LONDON DURING MAY, 1910.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 3·9 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates were 4·6, 4·1, and 4·2 per 1000 respectively. The lowest rates last month were recorded in Kensington, the City of Westminster, Hampstead, Holborn, and Wandsworth; and the highest rates in Finsbury, Southwark, Bermondsey, Lewisham, and Woolwich. Scarlet fever was less prevalent during May than in any previous month of this year; among the metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Pancras, Bermondsey, Lambeth, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1422 scarlet fever patients at the end of last month, against 1740, 1584, and 1489 at the end of the three preceding months; the weekly admissions averaged 177, against 204, 180, and 183 in the three preceding months. The prevalence of diphtheria also showed a decline from that recorded in other recent months; this disease was proportionally most prevalent last month in Hammersmith, Stoke Newington, Stepney, Southwark, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 908, 852, and 794 at the end of the three preceding months, had further declined to 734 at the end of last month; the weekly admissions averaged 73, against 93, 82, and 75 in the three preceding months. The prevalence of enteric fever showed but little variation from that recorded in the previous month; the boroughs in which this disease was proportionally most prevalent last month were Paddington, Hammersmith, the City of Westminster, Hampstead, and Battersea. There were 60 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 75, 84, and 66 at the end of the three preceding months; the weekly admissions averaged 8, against 12 and 6 in the two preceding months. Erysipelas was proportionally most prevalent last month in St. Marylebone, Hackney, Finsbury, Poplar, and Deptford. The 23 cases of puerperal fever notified during the month included 4 in Lambeth, 3 each in Hackney, Stepney, and Wandsworth, and 2 each in Poplar, Battersea, and Woolwich. The 12 cases notified as cerebro-spinal meningitis included 3 in Islington and 2 in Bermondsey.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the four weeks ending May 28th the deaths of 4402 London residents were registered, equal to a corrected annual death-rate of 12·4 per 1000; in the three preceding months the rates were 16·6, 13·9, and 14·0 per 1000. The lowest death-rates last month were 8·5 in Stoke Newington, 9·0 in Hampstead, 9·6 in Lewisham, 10·4 in Hammersmith and in Wandsworth, 10·5 in Fulham, and 10·6 in Camberwell; the highest rates were 14·5 in Holborn, 14·6 in Greenwich, 14·8 in St. Pancras, 15·1 in the City of London and in Bermondsey, 15·5 in Shoreditch, and 16·6 in Finsbury. The 4402 deaths from all causes included 449 which were referred to the principal infectious diseases; of these, 193 resulted from measles, 16 from scarlet fever, 26 from diphtheria, 154 from whooping-cough, 6 from enteric fever, and 54 from diarrhœa. No death from any of these infectious diseases was recorded last month in Stoke Newington; among the other boroughs they caused the lowest death-rates in Kensington, Chelsea, the City of Westminster, Hampstead, and Woolwich; and the highest rates in St. Pancras, Shoreditch, Bethnal Green, Bermondsey, and Greenwich. The 193 deaths from measles were 7 fewer than the corrected average number in the corresponding weeks of the five preceding years; this disease was proportionally most fatal in Paddington, Shoreditch, Bethnal Green, Southwark, Bermondsey, Battersea, and Greenwich. The 16 fatal cases of scarlet fever showed a decline of 24 from the corrected average number, and included 3 in Fulham, 2 in St. Pancras, and 2 in Bethnal Green. The 26 deaths from diphtheria were 17 below the corrected average for the corresponding period of the five preceding years; of these 26 deaths, 3 belonged to Hammersmith, and 2 each to Kensington, Islington, Stepney, Deptford, Greenwich, and Lewisham. The 154 fatal cases of whooping-cough showed a decline of 9 from the corrected average number; the greatest proportional mortality from this disease was recorded in Fulham, St. Marylebone, St. Pancras, Hackney, Finsbury, Shoreditch, Poplar, and Deptford. The 6 fatal cases of enteric fever were equal to one-half the corrected average number; 2 belonged to Bermondsey and 2 to Deptford. The 54 deaths from diarrhœa were equal to the corrected average; among the several boroughs this disease was proportionally most fatal in Fulham, Hampstead, Holborn, and Shoreditch. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 12 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: A. G. Wildey to the *President*, additional, for three months' course at Dreadnought Hospital, Greenwich; and A. Maclean to the *Jupiter*. Staff-Surgeons: W. R. Center to the *Collingwood*, temporarily; J. S. Dudding to the *Ganges*, for *Ganges II.*; and J. K. Raymond to the *Hearty*, temporarily. Surgeons: F. Cock to the *Latona*; and C. R. M. Baker to the *Antelope*, on commissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. I. D. Hackett has been appointed to the military hospital at Pretoria. Lieutenant-Colonel R. R. H. Moore has been posted to Bulford Camp, Salisbury Plain. Lieutenant-Colonel H. A. Haines, lately commanding the military hospital at Fyzabad, has been posted to Portsmouth. Lieutenant-Colonel R. H. Hall, from Colchester, has been transferred to take temporary charge of the military hospital at Mill Hill. Lieutenant-Colonel G. W. Brazier-Creagh, C.M.G., has notified his intention to retire from the service. Major A. E. Smithson has arrived home on leave from South Africa. Major C. Dalton has been appointed Staff Officer to the Principal Medical Officer in Ireland. Major E. M. Pilcher, D.S.O., at present serving in the Straits Settlements, has been selected to succeed Major C. G. Spencer as Professor of Medical Surgery at the Royal Army Medical College. Major W. Bullen has been transferred from Madras to the station hospital at Wellington. Major A. H. O. Young has been appointed for duty at Halifax. Major J. D. G. Macpherson has taken up duty at Pachmarhi. Major F. J. W. Porter, on termination of his appointment as senior medical officer, West Coast of Africa, has been granted leave and is taking out special post-graduate surgical work in Paris. Captain E. V. Aylen has been appointed a specialist in dermatology and venereal diseases to the Sixth (Poona) Division, India. Captain C. E. W. S. Fawcett has joined at Shwebo for duty. Captain E. C. Whitehead, from Pretoria, has been posted to Cork District. Captain S. M. Adye-Curran has been transferred from Kilkenny to the medical charge of troops, Bere Island. Captain H. B. Fawcus, lately on special duty connected with enteric fever at the Royal Army Medical College, has, on arrival in South Africa, been posted for duty to Bloemfontein. Captain R. J. C. Thompson has been seconded for service with the Egyptian Army. Captain E. J. Anthonisz and Captain R. G. H. Tate have arrived home on leave from India. Captain C. W. O'Brien, from Peshawar, has joined at Aden for a tour of duty. Captain L. G. Gibson, from Jullundur, has been appointed for duty at the station hospital at Dagshai. Captain A. S. Littlejohns has arrived home on leave from South Africa. Lieutenant M. O. Wilson has been transferred from the Quetta Division

to the Bareilly Brigade for special duty with the Worcestershire Regiment. Lieutenant A. P. O'Connor has been transferred from Dover to Shorncliffe. Lieutenant F. H. Bradley, on arrival in India, has been posted to Lucknow for a course of practical sanitation. Lieutenant A. Hendry, from Mhow, has joined at Neemuch. Lieutenant Harold Bevis resigns his commission (dated June 22nd, 1910).

INDIAN MEDICAL SERVICE.

Colonel W. G. King, C.I.E., has arrived home on leave from India. Lieutenant-Colonel G. W. P. Dennys has been appointed Principal Medical Officer of the Aden Brigade, vice Colonel W. A. Quale, transferred to the Abbottabad and Sialkot Brigades as Principal Medical Officer. Lieutenant-Colonel M. C. Wimberly has been appointed Officiating Staff Officer for the Divisional Medical Mobilisation Stores of the Fourth (Quetta) Division. Lieutenant-Colonel M. J. Kelawala has arrived in London on leave. Major W. R. Battye has been selected for the appointment of Residency Surgeon at Mewar. Major A. A. Howell and Major C. Thomson have arrived home on leave. Captain J. B. Christian has been posted for permanent duty under the Government of Eastern Bengal and Assam. Major H. C. Keates, District Plague Medical Officer, Gujranwala, Punjab, has been granted furlough for one year from India. The services of Captain H. W. Pierpoint have been placed temporarily at the disposal of the Honourable the Chief Commissioner of the Central Provinces. Captain J. Anderson and Captain W. M. Pearson, Bombay, have arrived home on leave. Captain F. N. White has been appointed to officiate *pro tem.* as Resident Surgeon at the Medical College Hospital, Calcutta. Captain W. Sapsley has been appointed for duty in the United Provinces. Captain D. C. V. Fitzgerald has been reverted from civil to military employment. Captain G. S. Husband has been appointed a specialist in the prevention of disease.

The King has approved of the retirement of the undermentioned officers of the Indian Medical Service:—Lieutenant-Colonel David Stuart Erskine Bain (dated April 5th, 1910), Lieutenant-Colonel Philip Durrell Pank (dated May 17th, 1910), and Lieutenant-Colonel William Symonds Percival Ricketts (dated June 10th, 1910).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned officers from the Unattached List, Territorial Force, and the Edinburgh University Contingent, Officers Training Corps, to be Lieutenants (on probation) (dated August 11th, 1909): Captain William Darling and Captain John May Darling. Paul Bernard Roth to be Lieutenant (on probation) (dated May 28th, 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Anglian Field Ambulance: William Ignatius Cowell to be Lieutenant (dated May 10th, 1910).

Unattached List.—Percival Templeton Crymble to be Lieutenant, for service with the medical unit of the Belfast University Contingent, Senior Division, Officers Training Corps (dated May 19th, 1910).

THE BRITISH RED CROSS SOCIETY.

We have received from the County of London Branch of the British Red Cross Society a number of papers and leaflets calling attention to the work of this branch, to which the County of London Territorial Force Association has delegated certain duties, such as (1) the selection, arrangement for equipment, and provision of a certain proportion of the *personnel*, of two general hospitals, each of 520 beds; (2) the establishment of convalescent homes for officers and men; (3) supplementary aid, where necessary, for the transport of sick and wounded; (4) the provision of rest and food stations along lines of transport; and (5) the raising and training of Voluntary Aid Detachments of both sexes. Some of the methods for assisting the work are as follows: 1. By raising and training Voluntary Aid Detachments, male and female. 2. By the promise of bedsteads, bedding, linen, crockery, cutlery, cooking utensils, &c., and all kinds of furniture and stores likely to be of use for hospital purposes, for the training of Voluntary Aid Detachments during time of peace, and for the use of the sick and wounded in case of invasion. 3. By the loan of transport for training purposes in time of peace, and by the promise of transport which can be utilised for the sick and wounded in case of invasion. 4. By the loan of large halls, buildings, sheds, fields, &c., for the purpose of practice during peace, and by the offer of large buildings and houses for conversion into hospitals and rest stations on mobilisation of the Territorial Force. 5. By the promise of drugs, dressings, surgical apparatus, and medical comforts on mobilisation. 6. By a donation or annual subscription to the County of London Branch of the British Red Cross Society. The address of the branch is Craig's Court House, Whitehall, S.W.

At a meeting of the Lewes Division of the British Red Cross Society, which was held at Worthing on June 17th, Dr. E. Stewart, the honorary organising secretary, gave an address. Among the many important points in connexion with voluntary aid with which the speaker dealt was the provision of convalescent homes. The great difficulty in time of war, he said, was the evacuation with sufficient rapidity of the base hospital, and he wished to see in every division of the county provision made for the opening of convalescent homes. It was stated that the Red Cross Society had now a total membership of 940 in Sussex.

A meeting in support of the formation of a Taunton branch of the Red Cross Society was held at Taunton in the Municipal Hall on June 18th. After the meeting a large number of ladies enrolled themselves as members.

THE TERRITORIAL YEAR-BOOK.

Messrs. Hodder and Stoughton, the publishers of "The Territorial Year-Book and Directory," are to be congratulated upon having produced at the price of 1*s.* a useful guide to the Territorial Force. This publication explains the conditions of service in the force, its organisation and administration, and contains a complete account of all the units. A useful feature of the work is a list of books (with prices and publishers), officially prescribed or otherwise, of utility to members of the force. We shall, perhaps, be pardoned a feeling of pride in quoting the reference to the R.A.M.C. Territorial and the nursing service, which appears under a review of the year: "The most altruistic of the professions has not belied its reputation since the Territorial Force was founded. Not only are the R.A.M.C. units well filled, but the auxiliary units, on which the whole force will largely rely, if ever the time come, have responded nobly to the appeal for personal service."

Correspondence.

"Audi alteram partem."

THE PEDIGREE OF RESEARCH ON INSECT-BORNE DISEASE.

To the Editor of THE LANCET.

SIR,—In connexion with the letter of Dr. Juan Guiteras in THE LANCET of June 18th it may be worth while to point out that our knowledge of this subject really descends to us in a continuous line from the great parasitologists—so far as I can ascertain, briefly as follows. Redi (1668) disposed of spontaneous generation in insects; Pallas showed that parasites may originate from eggs; Abildgaard (1790) found the first case of migration from one species of host to another; Eschricht (1841), Steenstrup (1842), and Küchenmeister (1851–53) demonstrated the general law of such migration for the higher parasites; Leukart published the development of *Cucullanus elegans* of the perch in *Cyclops* (1865–66); Fedschenko, part of the similar development of Guinea worm in *Cyclops* (1869); Manson part of the similar development of *Filaria bancrofti* in a *Culex* (1877); Smith and Kilborne showed that *Piroplasma bigeminum* is carried by ticks, without demonstrating the life-history microscopically (1889); Bruce showed that *T. brucei* is carried by *G. morsitans* (1894); Simond and Opie and MacCallum demonstrated zygosis in some protozoa (1897); I ascertained microscopically the life-history of *Plasmodium* in mosquitos, and the mode of infection (1897–99); Reed, Carrol, Lazear, and Agramonte gave the mode of infection of yellow fever without finding the parasite (1900–01); and numerous confirmations and extensions followed.

In all these cases strict proof was obtained by laborious observation and experiment; but such proof has been usually preceded by a mass of speculation which has

occasionally been right but generally wrong. The question really raised by the letter of Dr. Guiteras is, What value are we to attach to the speculation and to the proof respectively? In science speculation is the easiest thing in the world, and proof the most difficult; but there is a cult, especially in medical literature, which attempts to obtain credit by speculation alone. I think that this ought to be resisted in the interest of genuine workers and would therefore suggest the following obvious rule: that no credit should be given to any mere speculation, however right it may ultimately prove to be, (*a*) unless the author of it was not possibly in a position to verify it for himself (which is very seldom the case); and also (*b*) unless it really gave some clue to the actual worker which the latter could not have found elsewhere or was not likely to have discovered for himself in the course of his own researches (which is also very seldom).

Judged by this standard few of the numerous speculations on insect-borne diseases can claim anything more than honourable mention. That of Dr. C. J. Finlay is in a curious position. *S. calopus* does not convey yellow fever immediately, as he said, nor does it confer immunity, nor does it often breed in swamps, nor are its larvæ easily killed by potassium permanganate. It is therefore difficult to see on what evidence it was accused before 1900—probably on precisely the same evidence—namely, reasonable conjecture, which created the other speculations. On the other hand, Finlay certainly placed the actual species in the hands of the American Commission—but *why* he suspected it we cannot say.

I am, Sir, yours faithfully,

University of Liverpool, June 29th, 1910. RONALD ROSS.

NEW DEVELOPMENT IN LIBRARY WORK.

To the Editor of THE LANCET.

SIR,—With the permission of the council of the Royal Society of Medicine I have recently instituted a departure in library practice which I have been asked to describe to you, in the belief that other learned societies may think it worth while to try the experiment.

Fellows of medical and other scientific societies living abroad suffer many disadvantages as compared with their resident brethren, and none so great or so much felt as the deprivation of the use of their libraries. To all our Fellows living abroad we now offer to prepare for them *gratis* short abstracts of papers, and even of books, upon any medical subject and to search for, or check, references to medical literature.

The innovation has been most warmly welcomed, and from remote parts of the world we have received many grateful letters. Men living in the Chitral Valley, in the Sudan, the Cape, and equatorial Africa, who for years have had their work hindered by lack of library conveniences, say that what we now do for them is even better than they could have done for themselves had they been in London, for even here they would probably not be able to devote the many hours requisite for the research required to produce the results which our machinery can procure for them with a minimum of time and labour.

I am, Sir, yours faithfully,

J. Y. W. MACALISTER,

15, Cavendish-square, W., June 16th, 1910. Secretary.

THE FREEDOM OF THE FEEBLE-MINDED IN THE LIVERPOOL WORKHOUSE AND SOME OF ITS RESULTS.

To the Editor of THE LANCET.

SIR,—We hear a good deal at present about the "feeble-minded" and of the efforts that are being made to ameliorate their condition and to restrain them from evil courses. I am in entire sympathy with such efforts, but feel somewhat appalled by the magnitude and difficulty of the task.

Feeble-mindedness admits of many degrees, and without straining the term would, I think, include many of the inmates of workhouses and of workhouse hospitals. Surely people who allow a wound of the leg to fester until it becomes a chronic ulcer that will make them chronic invalids and national inefficients are mentally defective. We can always cure the chronic ulcers of people with brains, but we never can cure the chronic ulcers of these feeble-minded paupers. True, by means of such ulcers the sufferers can secure a bed and hospital treatment *ad libitum*, but certainly that is not the goal of any but feeble-minded men and women.

Then, if we take the attitude of the ordinary inmate of the surgical wards of the workhouse hospital we find the same feebleness of mind. A man or woman has a small malignant growth somewhere, the removal of which would be simple, safe, and full of promise for the future. We may talk to such people and explain the situation again and again, but we cannot make them see the reasonableness and necessity of the course recommended. They are indignant at the idea of an operation being suggested, take their discharge, and come back months after praying for anything to be done at a time when the disease has so advanced that nothing can be done. This is so different from the attitude of patients in the general hospitals that one is driven to the conclusion that the difference is one of brains. It may be said that Nature brings about a remedy by cutting off those who do not take ordinary precautions against disease. This remark does not apply to the patients with ulcerated legs who live at ease for many years, tended when they wish by trained and skilled nurses and doctors, all of whom feel that their work is in vain and that a cure is not desired nor will be permitted, and as the law stands these feeble-minded people are masters of the situation.

A completed note-book has just been received by me from the female lock wards of the Liverpool workhouse hospital, and contains notes of 165 cases. The majority of these cases suffered from secondary syphilis in its various forms, and the treatment afforded there ought to be a boon to these poor misguided women. In no other cases in the workhouse is feeble-mindedness so prominent as amongst these women. Many of them have a dull bovine appearance, without any sense of their degraded position or of the dangers of the disease from which they suffer. They come into hospital when trade is bad, and only stay in hospital until they are again fit for work. A Bank Holiday or a *fête* day means an exodus of all who are at all able to show themselves. At one time we had the power of detention of these diseased people, but when the Contagious Diseases Acts were abolished these poor women were left to their own caprices and the state of affairs I am describing is the result. Out of the 165 cases admitted 124 went out against advice with the disease active and uncured. The duration of stay was generally so short as to be useless for purposes of treatment. For instance, 23 stayed under treatment for a week, 18 stayed for a fortnight, 41 stayed for a month, 35 stayed two months, and 7 remained more than two months. To those who know the time necessary to cure syphilis these statistics show that the treatment of the disease in the Liverpool workhouse hospital is a horrible farce. These lock wards are maintained by the public for the treatment of the lowest class of the Liverpool prostitutes. They are not, however, used by them as a hospital where they can be treated for their diseases, but as a refuge to which they can flee when too diseased to ply their trade or when hard times or other circumstances compel them to seek a free shelter and to have a rest. Not only do these women allow the disease to develop freely in their own bodies but they spread the contagion broadcast amongst classes as ignorant as themselves.

Besides all this 29 of them were pregnant, and the disease had another victim in the unborn child. We have followed the mothers as far as we could to the lying-in wards, and we have found the results of the confinement in 24 cases. In seven cases the babies were born healthy as far as could be seen at birth and for as long after as they were under observation. In these seven cases the mothers had been under specific treatment respectively for 32 days, 36 days, 48 days, 84 days, 100 days, 171 days, and 181 days, and there is no doubt that the treatment of the mother was effectual in saving many of these children. Ten infants were born dead and bore signs of syphilis, six were born alive and were marked with syphilis, and one was born dead without any syphilitic marks. These women were all warned of the probable consequences to their offspring if they did not stay in and carry out the treatment rigorously until the time of confinement arrived, but neither the fate of the child nor consideration of their own future health could make any headway against their desire of the moment to take their discharge. It may be said, and said with reason, that the great mortality of these children is a good thing. But 13 were born alive. Of these, six were syphilitic, who would probably die after months or years of suffering, and of the other seven, many

would probably be delicate while they lived and a burden on the community.

Why should freedom of action be allowed to these women, many of them evidently feeble-minded, and all of them practically too feeble-minded to appreciate what every sensible woman can appreciate and endeavour to avoid—i.e., *anything that would endanger the life or welfare of their unborn children?* It seems as if the State were encouraging these poor short-sighted women in their evil courses and were extraordinarily unwilling to curtail their liberty to do evil. An artisan takes scarlet fever or some other of the eruptive or continued fevers in a mild ambulatory form and is detected. The health of his neighbours demands his immediate removal to a hospital, where, in spite of the curtailment of his *usefully* employed liberty, he is detained until he is well and innocuous to his fellow men. This is acquiesced in by all as necessary to the health of the community. Why are the lowest and most degraded of the female sex, whose liberty is licence of the most abominable kind, allowed to go about diseased and capable of spreading amongst their neighbours or of transmitting to their offspring a disease that is far more insidious and persistent than any of the eruptive fevers and probably far more disabling and deadly, if we include among the results of syphilis the cases of ataxy, of general paralysis of the insane, and the other miserable beings that die from its effects after many many years of suffering?

The voluntary system with regard to eruptive and continued fevers did not succeed, hence any people suffering from these diseases are, as soon as possible, compulsorily isolated and treated. The voluntary system has less chance of success amongst the victims of syphilis, and the compulsory detention of such cases would prove as effectual and would not prevent their applying for relief. In the old days when we had the power of detention we had as many admissions as we have now, and had also the great satisfaction of sending them out cured. There were many valid objections to the C.D. Acts as they were administered, both here and abroad, but the abolition of the power of detention in the cases I have above described was a great mistake. To allow low, degraded, syphilitic women such licence in the spread of disease amongst people poor and ignorant as themselves, to allow them to disregard the welfare of their unborn children, is a blot on the civilisation and humanity of the twentieth century that I hope will soon be erased. It is only those nurses and doctors who have experienced the stupidity, the heartlessness, the selfishness, and the dangerous character of these women who fully realise the hopelessness and the fatuity of their efforts to cure the patients under present conditions. The public, who do not look below the surface, believe that these women are being *treated* in the hospitals they have provided for them, and many of them would be shocked to know how futile is the provision so made. Many of the poor sufferers would be glad to be saved from themselves, as they have not the strength of mind to resist temptation. The maternal instinct itself is in abeyance, and the welfare of their progeny is not a factor of any moment in their lives, except as it may be an obstacle to their licentiousness.—I am, Sir, yours faithfully,

WILLIAM ALEXANDER, M.D. R.U.I., F.R.C.S. Eng.,
Visiting Surgeon to the Liverpool Workhouse Hospital.

June 18th 1910.

ALCOHOLISM AND OFFSPRING.

To the Editor of THE LANCET.

SIR,—There seems to be a tendency for some persons to believe that the recent investigations of Miss Elderton and Professor Karl Pearson prove that alcoholism in the parent does not lead to degeneracy in the offspring, whereas all that can be claimed is that except for a higher death-rate in the children of alcoholic parents there is no marked mental or physical degeneracy as compared with the children of sober ancestry.

Now this investigation, interesting as it may be, does not take us far, as it must be borne in mind that it is confined within the limits indicated by the words "childhood" and "children," and does not extend even into early adult life. The experience of men working amongst nervous diseases, I venture to think, is that it is during the next two decades that symptoms of degeneracy usually appear. It is either towards the end of a long educational training or when the real work of life begins that the child of the alcoholic parent first shows visible signs of early nervous exhaustion, morbid fears, or more serious mental disorder. I am quite prepared to be told that examination proves that in early life these children develop more rapidly and are more brilliant, but experience teaches that this rapid development and brilliancy is often the result of a hypersensitive nervous system which begins to show abnormal symptoms when it is exposed to the stresses of adult life. The earliest symptoms of nervous exhaustion are often purely subjective, and at first no importance is attached to them, or maybe they are misinterpreted, and even when the person himself begins to notice them he seldom speaks to another individual about them. This alone shows how difficult it is to make an accurate investigation as to the real comparison of the minds of the two classes of children. All that can be said at the moment is that there are no changes which are so gross as to be discoverable by the ordinary methods of investigation.

As one who appreciates the extreme difficulties of investigating early nervous changes owing to their subjective or purely personal nature, I may be pardoned for doubting the value of drawing any deductions from these observations as to the true effect of parental alcoholism on the mental life of the offspring.—I am, Sir, yours faithfully,

London, W., June 18th, 1910. MAURICE CRAIG.

MEASLES AND THE POST-OFFICE AUTHORITIES.

To the Editor of THE LANCET.

SIR,—Medical officers of health of large towns and school medical officers of large public elementary schools have definitely come to the conclusion after abundant and repeated experience that uninfected contacts do not carry measles infection, and it is quite a common practice nowadays to permit all children over 7 years of age who have previously had measles to attend school, even if living in an infected house.

The problem to be met in the case of measles is the great infectivity of the individual case, which for about three days *before* the characteristic rash appears is in a more infectious state than at any subsequent period when precautions usually begin to be taken. When "measles" is about every young child who has not previously had measles and who develops signs of a feverish cold should be forthwith isolated in bed for three or four days in any case, and, of course, longer if the measles rash develops; and in this way alone will it be practicable to bring this disease under absolute control.

I am, Sir, yours faithfully,

The Shirehouse, Norwich, June 17th, 1910. J. T. C. NASH.

THE REPRESENTATION OF MIDWIVES ON THE CENTRAL MIDWIVES BOARD.

To the Editor of THE LANCET.

SIR,—The letter of the Secretary of the Midwives Institute which appears in THE LANCET of June 18th merits some attention. There will be agreement generally upon the principle of representation which is advocated. The question, however, arises whether any reason exists which compels the medical profession to become the catspaw of the Midwives Institute.

It is quite true that certain members of the profession were its catspaws when the Midwives Act was passed, but a very large majority refused to be. The majority were, however, defeated and have accepted their defeat with philosophy, and have been much comforted by the sight of those wallowing in the Slough of Despond and in vain efforts to secure the success of a piece of badly considered legislation.

I venture to suggest that the delegation of the subject of midwifery into the hands of the Midwives Institute and the withdrawal of the subject from the compulsory subjects of medical examination are matters for serious consideration. The student is already overburdened with subjects, examinations, and fees to examining authorities. A very large number of practitioners do not practise midwifery; many are compelled to do so for various reasons, but would gladly relinquish the subject. Very few can now derive profit from paying much attention to the subject, owing to female competition. Time therefore appears to be ripe for the removal of a compulsory subject for which the profession has annually

less use. The women of England have, we have been told, demanded female assistance; they have succeeded in their demand to a considerable degree; there appears to be no reason operating against the most complete acquiescence in their demand. I am, Sir, yours faithfully,

Hatfield, June 17th, 1910. LOVELL DRAGE.

THE ACTION OF RARE EARTHS ON THE HEART OF THE FROG.

To the Editor of THE LANCET.

SIR,—In a recent number of THE LANCET there appeared a notice of some work of mine, published in the *Journal of Physiology*,[1] on the action of certain salts on the frog's heart. Will you kindly permit me to call attention to the point which prompted me to write the paper but which was overlooked in your article? The chlorides, nitrates, and sulphates of lanthanum, cerium (-ous), and yttrium (unlike those of aluminium), form neutral aqueous solutions. Such solutions added to Ringer's solution made up without alkali, will, when perfused through the frog's heart, stop it in diastole when the mixture contains only a hundred-thousandth or even a millionth gram molecule of the rare earth in a litre. The effect is very slowly removed by washing out with neutral Ringer's solution, but the beat is instantly restored by the addition of a little alkali.

The effect of these neutral solutions of trivalent metals on the heart very closely resembles the action of acids described 30 years ago by Gaskell, both in the manner of the stoppage, the slow and usually imperfect recovery on washing out with neutral saline, and the complete antagonism by alkali. It is shown experimentally that the neutral solutions of the same trivalent metals quickly cause a marked alteration in the ionic permeability of an artificial membrane of gelatin, a change like that produced by acids; in both cases the changed condition is but very gradually removed by washing with neutral sodium chloride solution, but instantly by the use of a dilute alkali. The trivalent metallic ion has, like the hydrogen ion, in a very marked degree the power of conferring a positive charge on a membrane.

The close parallel between the actions of acids and of the salts of the rare earths on an artificial membrane and their actions on the living heart seems to have a special significance in view of the strong probability that the rhythmic activity of the heart depends on the relations which obtain between the ions within and without the cells.

Since my paper was published I have made some experiments with the chlorides of erbium and of praesodymium. They act on the frog's heart in the same way as the other rare earths. I am, Sir, yours faithfully,

Cambridge, June 15th, 1910. GEORGE RALPH MINES.

THE ARREST OF CARBUNCLE.

To the Editor of THE LANCET.

SIR,—It has always been known that furuncle tends to be more severe both in its local and constitutional effects in proportion to the age of the patient, but this knowledge has become much more precise and considerable since the attribution of the complaint to bacterial infection. The acne, which is the mildest form of the disease, is for the most part an incident of puberty; the boil, which ranks next in severity, appears chiefly during early adolescence; and the more formidable carbuncle affects mainly middle or advanced age. Always also it has been inferred that the complaint is favoured by the degenerative changes which, setting in at various ages, always characterise increasing senility. Whether with age there is growing or diminishing liability to infection is a question which has, perhaps, been too little considered. There are no statistics to guide us and we have to fall back on the opinion of those who have given attention to the matter during a lengthened practice. A somewhat limited experience has led the present writer to believe that, on the whole, liability diminishes at first somewhat rapidly and then more slowly from puberty onwards. Individuals are met with in whom during the year or two before and after this age attacks of acne are frequent, in whom throughout the subsequent 15 or 20 years boils appear at gradually increasing intervals, and who after a lapse of several years since their last boil, when approaching, or perhaps well past, middle age, become the subjects of carbuncle. In these respects the complaint may be compared with typhoid fever, which is predominantly an accompaniment of early adolescence, and, speaking generally, becomes less frequent and more severe as age advances.

With regard to the latter disease Sir W. Watson Cheyne suggests that the increasing severity may be due in part to the lessened "recuperative power" induced by senile vascular changes. He emphasises tissue resistance in relation to infection in general, and illustrates by the case of tertiary syphilitic ulceration and analogous conditions which can only be explained on the supposition that there are local differences of resistance to bacteria in the tissues of the same individual.

That the tissues have something to do with carbuncle is evident not merely from its preference for older people, but from its local preference as affecting chiefly the neck, back, face, and so forth. On the other hand, the mere shape of the carbuncle shows that tissue resistance cannot have a very close relation to its spread and arrest. It is impossible that the susceptible parts of the skin should be always round, or that immune portions should without exception form rings surrounding susceptible circles. Nor, again, does the theory of differing resistance throw light on the diminishing liability to infection of increasing age, or on the still more curious anomaly that the increasing severity which accompanies length of years is not an indefinite one; that defence, however impaired by tissue change, is always able to impose limits on the growth of carbuncle.

In the clinical development of a carbuncle there are, as it seems to me, two well-marked stages which may be roughly discriminated as the bacterial and the leucocytic. The first is usually completed in two days or so from the onset of symptoms. By that time there is on the surface of the skin a round, hard, quite definitely limited swelling, being the exposed side of a compressed sphere of infiltrated subcutaneous tissue. As the swelling has commonly attained some size before pain and other symptoms begin, it is only seldom that one has an opportunity of observing the course of events from the local beginning onwards. All the evidence, however, goes to show that from the time the induration is large enough to be felt by the fingers it has the same smoothly rounded character, and that this is retained throughout its expansion, which goes on continuously and at uniform rate until arrest takes place. This is conveniently called the bacterial stage, because the swelling, composed in the main of coagulated tissues and blocked blood-vessels and lymphatics, is at the same time the area in which the staphylococci grow and beyond which they do not extend. The second stage extends from the end of stage one onwards to the period of completed cure. At its beginning the growth increases somewhat in size, but now loses something of its definitely limited character and tends to merge with gradually diminishing induration into the surrounding healthy tissues. The signs of inflammation, the heat, pain, tenderness, and so forth, are now much greater than during the first stage. I call this the leucocytic stage because the outer zone of less definitely limited induration which it introduces, represents in a special way the area of aggregation and activity of the leucocytes. This area, of course, contains besides leucocytes the other well-known products of acute inflammation.

Bearing these clinical matters in mind, we may now turn to an examination of current theories as to the mechanism of arrest. And, first, as to the theory that defence is due to locally formed antibodies, and that the size of the carbuncle is determined by the length of time required for the formation of these. The difficulty with which we are here immediately confronted is this: Given that the tissues with which the bacteria are in contact when the involved area is quite small, have not time to elaborate antibodies, what longer time have the tissues with which they are in contact at any later period? The answer is that there is, so far as observation goes, no difference. The tissues with which the staphylococci are successively in contact as the disease spreads are paralysed and disorganised with equal rapidity. On the hypothesis of a purely local defence, there is, in fact, no reason why a carbuncle should be arrested at all, but, as no very prolonged reflection is needed to show, quite the contrary; i.e., with each advance of the disease every reason why it should go on with increased rapidity.

[1] Journal of Physiology, xl., p. 327, 1910.

It is to be supposed that bacteria require a certain space for their growth and increase. If there be two spaces of unequal size the excess in number in the larger will, *cæteris paribus*, be in proportion to its size as compared with the smaller. Now in the case of a body like an enlarging carbuncle, whose shape is that of a somewhat compressed globe, the space occupied by the growing bacteria increases at a much greater rate than does the surface which is presented to the surrounding healthy tissues. Mathematics teaches that the increase of the surface of an expanding sphere is proportional to the square, whilst increase of its contents is proportional to the cube of the radius. Take, e.g., the case of a carbuncle at two periods in its growth, first when its radius is 2 centimetres and, secondly, when it is 3 centimetres in length. The superficial area at the earlier will be to that at the later stage as 4 are to 9, while the cubical contents will be as 8 are to 27. That is to say, while the resisting tissues have a little more than doubled, the attacking force, the bacteria, will have more than trebled in amount, and the like proportions will, of course, be maintained whatever the size of the growth. However rapidly the surface of a carbuncle expands, its volume will always increase much more rapidly. Why, then, should arrest take place at a point when the defending force is relatively weak in proportion to the attack and not rather at the very beginning of the complaint when the affected area is quite small and the resisting tissues very much stronger in comparison with the invading bacteria? Considerations like these raise grave doubts as to the adequacy of an exclusively local defence. They point rather to the probability that whatever may be the differences of recuperative power as between old and young, and whatever may be the disparity between different tissues in the same individual, the direct cause of the arrest of carbuncle is not local resistance, but something coming to the help of that resistance and conveyed to the part by the blood.

As the leucocytes imprisoned in the swelling of "stage one" have no effect on the progress of the carbuncle, and as the enormous massing of leucocytes of "stage two" does not occur until the disease has already become limited, we are led to conclude that arrest is brought about by an antitoxin, which after a time enables the tissues to recover their power of resistance to the spread of the bacteria. The greater severity of the complaint in older persons may be due in part to their feebler resistance, demanding more complete neutralisation of the poison before it is re-established, and still more, in all probability, to the slower formation of antitoxins, a slowness which is observed in relation to many physiological processes as age advances, and which manifests itself long before the onset of senile vascular changes. With regard to the latter it is extremely doubtful whether it has the importance in connexion with carbuncle which some have assigned it. Carbuncle frequently occurs without the slightest evidence of arterial degeneration, and when associated with vascular disease will apparently heal just as well as in the healthy. On our theory the severe cases of carbuncle which so often occur in the comparatively young receive a natural explanation without recourse to the strained and otherwise quite unsupported notion of a larger dose of bacteria. With regard to the lesser liability to infection of older persons, the most natural view is surely that the aged are less frequently infected because they harbour fewer bacteria. One thinks of the analogous case of ringworm of the scalp. While the parasite here inhabits the hair roots and the hair follicles of infected children, it is not found in the corresponding tissues of the old, or, indeed, of anyone beyond the age of 15. One has only to suppose that the follicles and glands of the skin of the elderly are in some measure less attractive to the staphylococcus than the like parts in younger persons to have, as it seems to me, a satisfactory explanation of the lessened liability of age to staphylococcal infection.

As to the toxins of carbuncle we may suppose the commonly recognised leucocidin to operate in the first stage as a neutralizer of the leucocytes. Perhaps some chemiotaxic action of a negative kind may come into play and account for the comparative smallness of leucocytosis at this stage. An experience which has repeatedly happened to the writer suggests that leucocidin may possibly take a more important part in carbuncle than has hitherto been suspected. If a carbuncle in the second stage be squeezed in order to make it discharge more freely certain symptoms are wont to manifest themselves after a few minutes. The patient complains of creepy, sickly, or faint feelings, due obviously to a mild form of intoxication. What has happened is that there was in the centre of the carbuncle a systemic poison in fluid form, the extrusion of which under pressure into the blood-vessels produced the symptoms in question. What is noticeable is that there has never been reason to think that healing was delayed, still less that the carbuncle had extended in consequence of the pressure, as might have been expected to be the case had free leucocidin been present to oppose the remedial action of the leucocytes. This raises the question whether leucocidin, having been neutralised at a stage when, according to the above view, mere interference with the leucocytes did no particular harm, does not possess some other property besides that from which it is named, and whether, in fact, it is not the tissue-destroying toxin of the first stage of carbuncle. On the other hand, this same circumstance, that the systemic toxin may be pressed from the centre of the carbuncle into the surrounding tissues without harm to the healing process, shows clearly that it is quite a distinct substance from the tissue paralyser. We have not, I think, in the whole range of human pathology so striking an example as this little experiment affords of the local formation of an extremely powerful general poison, scarcely at all neutralised by the formation of antitoxin in the blood and tissues. Were the toxin taken up as readily as it is formed the gravity of carbuncle would be very different from what it is. As things are, we have in the circumstance that the local poison is neutralised whilst the systemic one is overlooked a curious example of nature's economy, as if she exerted herself to meet the main danger of the unchecked spread of the carbuncle, while with a kind of large indifference taking her chance with regard to the lesser peril of the systemic intoxication. The continued existence of the virulent general poison long after the neutralisation of the tissue destroyer shows also that the immunity is antitoxic, not antibacterial. Did the antibodies attack the bacteria all the toxins would of course be destroyed *pari passu*. Lastly, the fact that a few minutes' delay takes place before the toxic symptoms manifest themselves may be looked upon as parallel with the similar delay noted by Dönitz in the case of animals between reception of toxins and their fixation in the tissue cells. The fact, however, that the constitutional symptoms in the case of carbuncle clear off with the healing of the local disease suggests that there is here at least no permanent union of the systemic poison with the body cells.

I am, Sir, yours faithfully,

May 30th, 1910. I. B. MUIRHEAD.

BRONCHOSCOPY.

To the Editor of THE LANCET.

SIR,—With regard to the movements of the bronchi described by Mr. R. J. Godlee in THE LANCET of June 18th, it is possible to add that the calibre of the secondary bronchi is subject to slight rhythmical variation (*vide* St. Bartholomew's Hospital Reports, 1906, Vol. XLII.). The first two patients on whom I practised bronchoscopy (1906) both showed this form of movement. One was a man having a stricture in a main bronchus; the other a woman wearing a permanent tracheotomy tube for a fibrous stenosis of the larynx. Since then I have several times observed the same phenomenon. Very likely it has some bearing upon the pathology of spasmodic asthma, and, as Mr. Godlee suggests, it is worthy of study.—I am, Sir, yours faithfully,

Harley-street, June 20th, 1910. T. JEFFERSON FAULDER.

THE SOCIETY FOR THE FURTHERANCE OF CHILD EMIGRATION TO THE COLONIES.—With the object of building up an efficient agricultural population in the colonies, a meeting was held at Oxford last year under the auspices of the Colonial Club to consider the question of child emigration. Since then a society with the above objects has been formed, and a fund has been opened. Efforts are being made to raise enough capital to finance a farm school in Newfoundland or Canada which will act as a model of the system on which the society hopes all child emigration will be based. Full particulars of the scheme can be obtained from the secretary, Mr. Kingsley Fairbridge, Exeter College, Oxford.

THE ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

(FROM A CORRESPONDENT.)

THE Forty-third Annual Meeting of the Canadian Medical Association was held in Toronto on June 1st, 2nd, 3rd, and 4th. The general sessions took place in the Convocation Hall of the University of Toronto and the meetings of sections were held in other buildings of the University, which were lent to the Association for the occasion by the Medical Faculty. There was a large attendance of members, and a long programme was gone through in a satisfactory manner.

First General Session: The Presidential Address: The Question of Milk.

At the opening general session in the Convocation Hall the chair was taken by the retiring President, Dr. R. J. BLANCHARD of Winnipeg. Addresses of welcome were given by representatives of the Provincial Government, of the city, and of the University, after which the President-elect (Dr. Adam H. Wright, Toronto) was inducted. Dr. WRIGHT, in a presidential address, considered the status of the general practitioner, the curriculum of the medical student, and the relation of the specialist to the general practitioner. He contradicted the impression that the general practitioner was dying out; far from being moribund in Canada, he thought that he showed symptoms of great vitality. On the question of medical education of the present day it was inevitable that he should think and say that there was too much cramming. Referring to the modern clinical lecture, Dr. Wright said that it frequently seemed to be the object of the lecturer to exhibit his own knowledge rather than to impart knowledge to the audience. At the conclusion of Dr. Wright's address the whole audience rose and sang "God Save the King."

Dr. CHARLES J. C. O. HASTINGS (Toronto) presented the report of the Milk Commission which was appointed by the Association in 1908 to inquire into the condition of the milk-supply of the Dominion, and to secure such legislation as might be found necessary to ensure a pure milk-supply. Dr. Hastings sketched the work done by the Commission, and said that until accurate definitions of what was meant by the terms "milk," "certified milk," "officially pasteurised milk," and "commercially pasteurised milk" had been adjusted to the satisfaction of the Dominion analyst, the Federal Government was unable to assist by legislation in the effort to obtain a pure milk-supply. However, the outlook was hopeful, and the measures taken in Toronto had resulted in a vast improvement of the milk-supply of that city. These measures were chiefly in the direction of pasteurisation, of which method Dr. Hastings showed himself to be a strong advocate.

Dr. CHARLES E. NORTH (New York) read a paper on a pure milk-supply, in which the milk-supply of New York was discussed. He confessed himself an upholder of pasteurisation, because in large cities the inspection of milk-supplies at their source was usually ineffective.

Veterinary Director-General J. G. RUTHERFORD (Ottawa) showed himself as a hard-and-fast believer in the theory of the transmissibility of bovine tuberculosis to the human species, and argued that the only method of really stamping out human tuberculosis was to eradicate the disease in cows.

Second General Session: The Address in Medicine.

An evening general session was held on June 1st, when Dr. W. P. HERRINGHAM (London), physician to St. Bartholomew's Hospital, delivered the Address in Medicine. He chose as his subject Chronic Diffuse Parenchymatous Nephritis, and illustrated certain phases of the disease by descriptions of cases which had come under his immediate notice. After mentioning that acute nephritis was rare in England, he gave a clear exposition of chronic Bright's disease in different stages and of varying degrees of virulence. He pointed out that the great dangers of an attack of nephritis were the delicacy left behind and the liability to recurrence, while the pathology of the disease was not clearly known. Some medical men might comfort themselves by casting the blame on false metabolism or on intestinal auto-intoxication, but these explanations did not account for relapse. A patient with chronic Bright's disease was in many respects like a town of which the drainage was out of order. Dr. Herringham laid stress on the importance of diet in treating the disease, but while recognising this, he was not an advocate for restricting diet to fish or special foods. He was accustomed to order light ordinary diet and allowed the patients to partake of meat. Strict moderation as to quantity of food was necessary but not as to variety. In serious cases of the malady the main object was to avoid uræmia by maintaining a fair excretion of urine with the help of suitable drugs. Difficulty in controlling hæmaturia and in relieving œdema would also be met with, and would tax the physician's resources. Referring to the high blood pressure found in patients with this malady, Dr. Herringham said that he did not regard this as a serious symptom in the young, though in the old, when the arteries were brittle and frail, such pressure was undoubtedly dangerous. A high blood pressure might be considered rather as a compensatory action than as a symptom in itself.

Third General Meeting: The Address in Surgery; Exopthalmic Goitre.

At the general session on the afternoon of June 3rd the Address in Surgery was given by Dr. JOHN B. MURPHY (Chicago). The subject was the Surgery of the Joints, and the general lesson of the address was that mistakes were not infrequently made by surgeons when treating injuries of joints through a faulty conception of the structural conditions. Dr. Murphy's argument was that as the capsule of a joint is a non-vascular fibrous tissue of an inelastic nature it is wrong to use force in correcting deformities of joints. The conditions should be relieved before pathological processes had developed producing ankylosis, as every acute infective process of a joint might lead to ankylosis by pressure. The method of treatment employed by Dr. Murphy has been to aspirate with formalin and glycerine or turpentine and not to drain a joint by opening. Aspiration should be done promptly and the limb should be kept in an extended position. In the case of the patella injections of formalin and glycerine should be made eight or nine days before operation. If this were done there would be no effusion. Throughout the address Dr. Murphy illustrated his arguments by beautiful photographs of joint injuries of various kinds which had come under his hands and which he had brought to a more or less successful issue. Dr. Murphy's presentment of his attitude on the subject of joint injuries was most graphic, and was followed with the closest attention and interest by a very large audience.

Dr. S. P. BEEBE (New York) opened a symposium on Exophthalmic Goitre, discussing mainly its pathological aspect. He pointed out that iodine was readily taken up by the thyroid gland, and that therefore the drug should be given in Graves's disease with great caution. He mentioned that a serum for the treatment of the disease had been prepared, which so far as could be judged from its as yet limited employment had been satisfactory.

Professor ALEX. MCPHEDRAN (Toronto) said that exophthalmic goitre was not prevalent in Canada. In the Toronto General Hospital during the past five years 55 cases out of a total of 8000 medical cases had been treated there. Referring to the comparative beneficial effects of medical and surgical treatment, Professor McPhedran said that writers on surgery did not place much faith in medical treatment and that statistics seem to justify this opinion, but he went on to say that it was no proof of the inefficacy of medical treatment that the results did not lend themselves kindly to favourable statistics.

Dr. F. SHEPHERD (Montreal) allowed freely that the surgical treatment of the disease was not an ideal treatment, and he looked forward to serum treatment as the only rational means for removing the cause. He nevertheless was of the opinion that in most cases operation had a very favourable effect. He had not found local anæsthesia satisfactory when operating for Graves's disease. He considered that the operation should be performed rapidly and that the para-thyroids should be left as nearly in position as was possible. In view of the fact that early cases of Graves's disease were much more amenable to surgical treatment than old cases, he thought that it would be as well if physicians sent cases to surgeons before they were far advanced.

A long discussion followed, the merits or otherwise of medical and surgical treatment of exophthalmic goitre being

closely debated. A point of interest made by Dr. HERRINGHAM was that he had not observed in the patients whom he had examined after operation that the tachycardia was relieved. Several other speakers agreed with this conclusion.

Fourth General Meeting: Address in Gynæcology; A Committee on Medical Education.

At the general session on the evening of June 3rd Dr. HENRY C. COE (New York) gave the address in Gynæcology. He propounded the view that the surgical side of gynæcology would soon become less prominent and that more attention would be given to diagnosis, and that the trained man of mature experience would hold his own against the half-fledged specialist. He was of the opinion that operative procedures were too much in vogue in the United States at the present time. The speaker also believed that State control of marriage would come to pass.

Dr. J. C. CONNEL (Kingston, Ont.) read a paper on medical education, in which he compared the curricula of Canadian universities of 25 years ago with those of the present day, by no means altogether in favour of the latter. He therefore proposed the appointment of a committee of the Association to deal with the subject of medical education. The proposal was accepted by the Association, and a committee for the purpose was formed.

Proceedings in the Sections.

The programme of the sections was very long, but the papers read were of a good average standard, while some papers were of outstanding merit. Perhaps the best papers presented were those dealing with the psycho-neuroses. In the Section of Medicine on June 1st a symposium on the psycho-neuroses was held. The first paper read was by Dr. J. J. PUTNAM (Boston) on psycho-analysis. This paper was mainly a presentation of Professor Sigismund Freud's views and treatment. Dr. Putnam has been a friend and follower of Dr. Freud for some time, and has treated patients by his methods during a period of a year with a considerable amount of success.

Dr. AUGUST HOCH (New York) read the next paper on the same subject, and was followed by Dr. W. H. HATTIE (Halifax), who read a paper on the psycho-neuroses in asylum practice.

Dr. A. ERNEST JONES (Toronto) then read a paper on the general significance of the psycho-neuroses. Dr. Jones, like Dr. Putnam, is a disciple of the Vienna professor, and his paper was an exposition of the tenets of that school.

In the discussion that followed several speakers took part, including Dr. C. K. CLARKE and Dr. MEYERS, both of Toronto, but neither of these dealt with Freud's theories in detail or to any extent. Dr. JOSEPH COLLINS (New York), however, attacked the theories and practice of Freud and his followers warmly. He based his objections to some extent on the ground that although these are but theories, and although when put into practice they have been fruitful of somewhat meagre results, Freud's followers regarded him as almost an inspired prophet, and looked upon those who differed from him with a certain amount of intellectual contempt, mingled, may be, with some pity for their inability to grasp, to them, such self-evident facts.

On June 2nd Dr. COLLINS, in the Section in Medicine, read a paper entitled, "The Psycho-neuroses: an Interpretation," in which he set forth his views at length. According to Dr. Collins, the objections to Freud's theory and practice are "that his note of interpretation is too arbitrary, that the psycho-analysis may become a source of auto-suggestion, and that it gives a prominence to the sexual factor as a causative agency which it has not yet been proved to be. Further, even admitting that sexual factors have the importance in the psychogenesis of hysteria that Freud maintains they do have, very little has been vouchsafed us upon which to base the belief that psycho-analysis is a reliable therapeutic agency." Dr. Collins, in his paper, cavilled at the classification of the psycho-neuroses made by Freud and took the view that nothing whatever was to be gained by an effort to classify these cases into separate disorders.

Dr. GEORGE W. ROSE (Toronto) read a good paper in the Section of Medicine on the Treatment of Acne Vulgaris by Vaccines. Dr. Rose holds that this treatment is dependent upon the micro-organisms found in the pustules of each case before commencing treatment. If the bacillus of acne is alone present, as in many cases of acne punctata, then the bacillus of acne vaccine is used, but if the staphylococcus albus coexists, then the albus vaccine must be also used. Out of 56 cases treated by Dr. Rose satisfactory results were obtained in 44 cases. In the remaining 12 cases improvement occurred in all but two.

Among other papers read was one by Dr. J. A. AMYOT (Toronto), provincial analyst, on Rabies, in the Section of Pathology on June 3rd. After outlining the cause and treatment of the disease, he made the statement that Professor McKenzie, of the pathological department of the University of Toronto, had many years ago discovered the germ of rabies and, in fact, anticipated the discovery by Negri, the Italian pathologist, by some years.

The number of papers read in the Section of Pathology was larger than in any other section, and these were, moreover, of a high quality. Unfortunately, the room devoted to this section was somewhat out of the way, and the audiences were consequently small.

The meeting terminated on June 4th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENT.)

Bristol Royal Infirmary.

AT a governors' meeting on June 14th it was decided to proceed with plans for the renovation of the Royal Infirmary. The present building, which holds 270 beds, has become inadequate in the eyes of the committee for its duties; and it is therefore proposed to build a new block to contain 180 beds for surgical work on an adjoining site which is already being prepared, at the same time retaining only 170 beds in the old building. The two blocks, which are separated by a street, will be connected by subways. The president, Sir George White, gave a detailed description of the proposed block, which will, it is felt, be a more satisfactory solution of the difficulty than a mere patching of the old building. It is to contain five large wards of 24 beds each, 17 smaller wards, three large surgical theatres, and a new casualty department. Gardens will also be provided for the patients. According to the estimates this will cost £50,000. In addition demolition of properties to provide the site will lead to a capital expenditure of £15,000, and £5000 needed for immediate changes in the present building brings the total sum required up to £70,000. Towards this the committee has collected £35,000. The Lord Mayor and Sir Isambard Owen, Vice-Chancellor to the University, spoke in favour of dealing radically with the renovation of the institution; and Mr. Samuel White, the President's brother, has generously offered £5000 on condition that another £30,000 are raised within 12 months. He further suggested that this extension scheme should constitute the City's memorial to the late King, a proposal which (judging from letters in the local papers) may undergo some modifications in view of the feeling that such a memorial fund should not be limited to one medical institution only.

The Centenary of the Bristol Eye Hospital.

From Wednesday, June 15th, to Saturday, June 18th, the Clifton Zoological Gardens were devoted to a fête in recognition of the hundredth birthday of the Bristol Eye Hospital, which was founded on June 19th, 1810. Splendid weather prevailed throughout, and there were good attendances daily. The committee organising the fête hopes to make a net profit sufficient to wipe out the existing debt of £1200 and to build a nurses' home which is urgently needed; and though at the time of writing it is not possible to say what has been the actual outcome, it is confidently expected that a large sum has been raised. The fête was opened by Mrs. F. Richardson Cross on Wednesday, and by the Lord Mayor on Saturday, and on Saturday Mr. Richardson Cross entertained at dinner all those gentlemen who have in the past 20 years acted as house surgeon to the hospital.

Registrarships at the Bristol General Hospital.

The Bristol General Hospital has of late taken various steps towards a fuller development of its resources for clinical teaching and investigation. The most recent of these is the formation of medical and surgical registrarships. The first holders of these new offices are Dr. Arthur Fells and Dr. W. J. H. Pinniger respectively.

Irish Medical Men in Bath.

On June 18th about 60 members of the Irish Medical Schools and Graduates' Association visiting Bath were welcomed by the Mayor. In the afternoon the reception committee held a garden party in the Institution Gardens and the Baths were visited. In the evening the party dined at the Empire Hotel, the toast of "Our Bath Hosts" being proposed by Dr. H. Macnaughton Jones and responded to by the Mayor and Dr. E. J. Cave, Mr. T. Pagan Lowe proposing the health of the President of the Association. The Mayor held a large reception at the Royal Promenade.

The Superintendentship of the Bristol City Fever Hospital.

The Bristol health committee has decided to offer £200 as a commencing salary for the post of resident medical superintendent to the Ham Green Fever Hospital. The last holder of the office, Dr. James Fletcher, began nine years ago with £150; but during his tenure the responsibilities have increased so greatly that an increase of the commencing salary was to be expected in common justice.

June 20th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Taylor Memorial Home.

THIS home, dedicated to the memory of the late Professor J. W. Taylor, was opened by Mr. A. D. Steel Maitland, M.P., on June 11th. The home is near the Women's Hospital, Sparkhill, and will permanently accommodate six women whose condition is incurable. The annual cost of maintenance is estimated at £300. Yearly subscriptions to the amount of £150 and donations amounting to £1500 have been promised, so that there is an assured income of £200. The sum of £100 a year has still to be provided.

Hospital Saturday Fund.

The thirty-eighth annual collections were taken on June 18th, and there is little doubt that a total of £20,000 will be reached before the fund closes. Since the fund was established £414,592 9*s.* 2*d.* have been raised in pennies and halfpennies, and it has been possible to make regular grants of £10,000 per annum for the support of hospitals. Twenty-four hospitals and nursing societies benefit, cases of consumption are sent to the Eversfield Hospital, St. Leonard's-on-Sea, and rheumatic patients to Droitwich Brine Baths. The convalescent homes at Llandudno for men and women, and at Great Barr for children, have helped to restore 35,785 persons to health. The executive has now determined to perpetuate the memory of Sir William Cook, who was President of the Fund, by the erection of a home for consumptives. The scheme has been under discussion for a long time, but there have been many difficulties. Negotiations are now taking place in regard to an ideal site, at a convenient distance from Birmingham.

June 21st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Education Committee and Defective Vision in School Children.

THE Liverpool education committee have approved of the special subcommittee's report dealing with defective vision in school children, and have recommended to the city council as follows:—

That a sum not exceeding £250 per annum be granted for meeting the cost of testing the eyesight of children attending the elementary schools who are reported by the school medical officers to have defective vision, and whose parents are found to be unable to defray the cost; that every such child shall receive a voucher to be redeemed at the price of 3*s.* if signed by a registered medical practitioner recognised by the local education authority for this function; and that a list be prepared of such hospitals and registered practitioners as the subcommittee consider to be properly equipped for such work, and as have expressed their desire to undertake it.

These recommendations show that the Liverpool education committee do not realise the number of children with defective vision attending their schools. That a sum of £250 should be considered sufficient to meet the cost of eye-testing is in itself evidence how wide of the mark they have fallen in their calculations. A sum of £250, to provide for a fee of 3*s.* (which, by the way, is considered an inadequate payment) per child, would pay for not much more than 1600 children. Now, recent statistics of all the children attending elementary schools in Liverpool showed that from 16,000 to 18,000 were defective in vision. These latter figures do not necessarily imply that all these children require glasses, but that they require treatment and also the judgment of an experienced ophthalmologist as to the necessity, or otherwise, for the use of glasses. It is a moot point whether a general practitioner can in all cases be considered fully competent to deal with testing and measuring children for defective sight.

The Tuberculosis Exhibition.

The Tuberculosis Exhibition which is being held in St. Martin's Hall, and allusion to which was made in THE LANCET of June 18th, is proving a great success, the residents of the poorest districts being attracted both by the exhibits and the lectures nightly delivered by well-known local physicians. The *Liverpool Post and Mercury* of the date of June 20th makes the following comment:—"Only in one respect are the lectures open to criticism. ..... The lecturers should not forget the educational accomplishments of their audiences, and it would be well for them to use simpler phraseology. ..... Such words as 'segregation' and 'debility' are unlikely to be generally understood, and as the same ideas can be conveyed in more familiar terms it would be a pity if the gospel of sanitation were to fail in its effects through a badly-chosen vocabulary." The criticism appears sound.

An Entomological Expedition to Malta.

The Liverpool School of Tropical Medicine has decided to send Mr. Robert Newstead, M.Sc., its lecturer in economic entomology and parasitology, to Malta at the end of the present month to investigate the sand-fly. The major portion of the funds to defray the cost of this expedition has been borne by the Advisory Committee for the Tropical Diseases Research Fund (Colonial Office), which voted a special grant of money for the purpose. Facilities for the expedition have been afforded by Messrs. James Moss and Co.

June 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Royal Infirmary: Post-Graduation Classes.

THE summer session of post-graduation classes at the Glasgow Royal Infirmary has just been concluded, and the syllabus is now being drawn up for the autumn course. This course is to be held during the month of September, and the introductory lecture is to be given by Sir James Barr of Liverpool. The classes will be similar to those of former years and will include instruction in clinical medicine and clinical surgery, hæmatology, bacteriology, vaccine therapy, diseases of the ear, eye, throat and nose, skin, gynæcology, electrotherapy, &c. A copy of the syllabus may be had on application to Dr. J. M. Thom, superintendent at the Royal Infirmary.

Dundee Infirmary Finances.

At the last meeting of the court of governors of Dundee Infirmary it was decided, in view of the total deficit on the working of the institution amounting to £7787, to transfer £7000 from the reserve fund. In moving the adoption of the report, the chairman remarked that while during the last ten years the ordinary expenditure of the infirmary had gone up from £11,000 to £16,000 per annum, or nearly 50 per cent., the ordinary income had shown no corresponding increase. Subscriptions and other annual contributions were not keeping pace with the increasing needs of the infirmary, and legacies and larger donations had to be looked to for the necessary support. In view of the fact that it was desirable that a larger number of citizens should be interested in the welfare of this noble institution, the directors were glad to say that 80 new annual subscribers had been enrolled. The report was adopted.

Measles and Dundee Children.

A large number of children in Dundee have during the recent severe epidemic died, and it appears as if in many

cases life might have been saved had timely aid in the case of necessitous children been forthcoming. In some cases piteous appeals were made by mothers for assistance, but according to Professor D. MacEwan "all the agencies of the town passed them by on the other side" because it was nobody's business. Professor MacEwan has "no hesitation in saying that many children during the last epidemic owed their deaths simply to neglect," and also "there were a great number of distressing cases neglected as far as nursing and medical attendance were concerned." "The Sick Poor Nursing Society" has brought the matter to the notice of the public. Its nurses have had to turn a deaf ear to appeals because the rules are against nursing infectious cases. Dr. C. Templeman, medical officer of Dundee, has long urged better provision for such cases, and has said that "this lack of accommodation for a certain class of measles cases is perhaps the one black spot in our otherwise admirable method of checking infantile mortality; in this matter of measles we are sadly lacking in facilities for coping with the disease." He regards as the first thing to save the lives of the poorest children the taking them away from homes where recovery is practically impossible, especially with children of that class suffering from serious complications. The children of a home where the mother is at work all day and there is no one to tend them ought also to be provided with hospital accommodation, but as for the rest of the children, a whole epidemic of measles cannot be provided with accommodation, only certain classes can be dealt with. Dr. Templeman remarks that the last epidemic has been of an unusually virulent type, with diphtheria associated with a great number of the cases; and he suggests that an isolation block should be built in the grounds of the hospital similar to the block which it is proposed to erect for advanced cases of phthisis, and as the accommodation would only be required for a few months every three or four years, the expense would not be great.

June 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Midwives Act and Ireland.

STEPS are being taken in Dublin to formulate the opinions of the medical profession on the extension of the Midwives Act to Ireland. It is expected that a conference will shortly be held between representatives of the Royal Colleges and of the various medical societies, and it is hoped that a definite decision may be arrived at which can be taken as voicing the opinion of the profession. In the meantime, the governors of the Rotunda Hospital, who are naturally and properly anxious to remove the disadvantages under which Irish midwives suffer at present, have circularised the Representative Peers of Ireland in favour of the extension of the Act. The governors point out that in order to gain the certificate of the Central Midwives Board an Irish midwife has to travel to England, while the certificate is already being made compulsory for certain Government appointments in Ireland. But the regulations of the Central Midwives Board are considered to be unsuitable in some particulars to the conditions of training in the Irish lying-in-hospitals, so that extension of the Act to Ireland will be attended with some administrative difficulties.

The Dublin Hospitals' Tuberculosis Committee.

A quarterly meeting of the Hospitals' Tuberculosis Committee was held on June 17th, Sir John Moore being in the chair. The honorary secretary, Sir William J. Thompson, read a satisfactory report from the inspector of the Queen Victoria Jubilee Institute for Nurses, showing that the work of the two special tuberculosis nurses, supported by the Women's National Health Association, continues to be carried on successfully. The report of Mr. J. T. Daniel of his visits over a period of three months was also read and approved, as were summaries of the work done by district nurses in Dublin and Terenure amongst tuberculosis cases for three months. The following resolution was unanimously adopted, and the honorary secretary was directed to send it to the public health committee and the cleansing committee of Dublin corporation:—

That this committee is of opinion that a large proportion of the number of chest affections leading to tubercular disease in the city of Dublin is due to the excessive amount of dust in the streets, the inadequate watering thereof, and the faulty method of sweeping the streets.

The committee note with regret that the plague of dust is especially prevalent in the poorer quarters where little or no attempt is made to lay it by watering and subsequent removal.

The medical superintendent officer of health of Dublin and the Local Government medical inspector for the Dublin district were elected members of the committee. Lady Aberdeen laid before the committee the drawings and proposed plans of the P. F. Collier Dispensary for the Prevention of Consumption, which is to be erected forthwith in Charles-street, Upper Ormond Quay, Dublin.

The Tuberculosis Death-rate.

In answer to a question in Parliament last week Mr. Birrell stated that the total number of deaths from all forms of tuberculosis in Ireland had decreased from 11,679 in 1907 to 10,594 in 1909. In answer to a supplementary question, however, he seemed to acquiesce in the suggestion that a new method of classifying mortality returns might account for some at least of the decrease. This answer naturally gave rise to fear that the improvement announced might after all be quite insignificant. Next day, however, an official statement was issued to the effect that what the Chief Secretary meant was that if there had been a change he did not think this would account for the decrease which had taken place. As a matter of fact, no change in the classification has taken place since 1902, and the figures given for each of the years 1907, 1908, and 1909 relate therefore to precisely the same classification. The decrease in the number of deaths from tuberculosis in Ireland, therefore, amounts to 1085 in two years. This remarkable result must be encouraging to those engaged in fighting the disease.

The Galway Hospital and Medical School.

The Bishop of Galway has put forward a scheme for the reorganisation of the Galway Hospital so as to render it a more efficient centre for clinical instruction. He suggests, among other things, that: 1. The hospital be managed by a committee, consisting of eight persons nominated by the county council, of four selected by the governing body of University College, Galway, and of three coöpted members. 2. That the medical staff of the hospital be elected by the committee from the professors and lecturers of the University College, and that additional appointments may be made to the staff by the managing committee subject to the approval of the Local Government Board. Every appointment on the staff to be for four years, the holder to be eligible for re-election. 3. That the committee of management annually appoint a registrar from the medical staff, whose duty it shall be to supervise the clinical instruction. The last recommendation quoted is hardly practicable, the staff of the hospital being at present composed of the medical professors of University College.

Lisburn Fever Hospital.

Dr. M. B. Mackenzie, medical officer of Lisburn Fever Hospital, has reported to the board of guardians of Lisburn that the present condition of affairs in that institution cannot continue, and that, in his opinion, it will be necessary to provide at least four new wards in addition to those already existing. As at present arranged, there was neither a ward for disinfection nor one for observation. When a patient was brought in suspected of suffering from an infectious malady it was necessary to disinfect an empty ward, and if that ward was in use, as it often was for other purposes, there was no place whatever available. In reference to disinfection, they were in a worse position at present, and patients had to be taken into the nurses' private apartments and disinfected there, a place from every point of view unsuitable. There were only six wards for infectious disease at present, one being a large ward divided by wooden partitions, and these wards had to accommodate men, women, and children. Dr. Mackenzie asked for two more wards, in addition to ones for observation and dismissal. The matter was referred to a committee for consideration.

Health of Belfast.

At present Belfast is in the grip of a severe outbreak of measles. The medical officer of health reported to a meeting of the public health committee last week that, under a system of voluntary notification which the committee had arranged with district medical officers of health and others, during the week ended June 11th 362 cases of measles were notified, of whom 331 were visited by officers

of the department, and in 280 of these total disinfection was carried out. If the system of notification was compulsory there is no doubt it would reveal a much greater number of cases.

Death of Francis Edwin McCune, B.A., M.D. R.U.I.

The death of Dr. F. E. McCune took place on June 12th in Oban at the residence of his father, Rev. Samuel McCune, formerly minister of the Presbyterian Church, Magherafelt, Co. Derry. Dr. McCune graduated M.B. of the Royal University in 1902 and M.D. in 1905, having previously, in 1899, obtained the B.A. in the same University. He entered the Navy in 1904 and was appointed first to the H.M.S. *Excellent* and afterwards to H.M.S. *Black Prince*, stationed in the Mediterranean. He was invalided out of the service in 1908, having pulmonary tuberculosis. A very able student and a naval surgeon of great promise, Dr. McCune has been carried off at the early age of 33 years, to the regret of those who knew him.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Percolation Cesspools.

AT a meeting of the Society of Public Medicine held on May 25th, M. Périssé introduced a subject of great hygienic importance—namely, the question of percolation cesspools (*puisards absorbants, fosses non étanches*). He said that these receptacles were everywhere prohibited in France, but nevertheless existed everywhere, because in places where there were neither sewers nor a systematic removal of refuse it was only by soaking into the ground that slop-water and excreta could be got rid of. Instead of the indiscriminate prohibition of them there ought to be compulsory inspection by the municipal authority, followed either by sanction or by an order for discontinuance. The special forms called *fosses non étanches* were dangerous to health in the highest degree, because they filled the subsoil of houses with the pathogenic microbes contained in slop-water. In France there were more than 1,000,000 *fosses non étanches*, which were the principal cause of the contamination of drinking water. An excellent method of dealing with domestic slop-water was in use at Saint Cloud, where the water from septic pits on the Mouras system was delivered under the soil of gardens and cultivated fields by means of drain-pipes not far below the surface. All the advantages of purification by the action of the earth were thereby obtained without the drawbacks incidental to the superficial distribution of slop-water over irrigation meadows.

Radium in the Surgical Treatment of Cancer.

The use of radium in the treatment of cancer gave rise to an animated discussion among several eminent surgeons at meetings of the Surgical Society held on June 1st and 8th. M. Monod inaugurated this discussion by saying that M. Wickham in making a communication on the subject had mentioned that each of five patients treated in this way had shown a considerable improvement and a retardation of the appearance of the relapse. In his opinion the application of radium wasi ndicated when the removal of the tumour was impossible; it might also be resorted to after complete removal with a view to prevent a relapse. In some cases radium should be used to supplement a surgical operation, not being applied until as much as possible of the tumour had been removed. M. Segond said that several patients under his care had been treated by applications of radium. He had not seen any instance of recovery, but it appeared to him that the radium had been beneficial to some extent. Under its influence there had been relief of pain and temporary cicatrisation of the ulcers, but the disease nevertheless continued to extend subsequently. In cancer of the uterus it seemed to be useless, for the tumour went on growing behind the cicatrised ulcer, and in one instance produced a recto-vaginal fistula. M. Delbet said that his experience differed from that of M. Segond, for he had seen good results from the use of radium in epitheliomata of the uterus. M. Tuffier said that he had applied radium before, during, and after operations. In some cases of inoperable cancer of the uterus there was an evident modifying and beneficial action, but the extension of the disease was not prevented. During the operations M. Tuffier inserted the radium tubes in the drainage apertures. Some patients relapsed quickly and others slowly. After the operations the pain ceased and there was temporary improvement without permanent recovery. M. Lucas-Championnière said that in his experience radium had a palliative but not a curative effect. M. Ricard said that he had observed a very gratifying palliative effect from the use of radium, but not any instance of recovery. M. Nélaton said that in a case of epithelioma of the cervix uteri approaching the limit of operability he employed deep curettage with subsequent application of 0·05 centigramme of radium, and for the last two months the patient appeared to be quite well. M. Morestin, M. Sieur, M. Walther, M. Routier, and M. Guinard all mentioned cases in which the employment of radium was followed by evident improvement, which, however, was only temporary.

Acute Poliomyelitis.

Acute infantile paralysis has for a considerable time existed in Paris in an epidemic form, and at a meeting of the Academy of Medicine held on May 31st M. Netter, in reading a communication on the subject, said that to his knowledge more than 100 cases had occurred in the city and the *banlieu* since the summer of 1909. Last January there was an increased prevalence of the disease in consequence of the peculiar climatic conditions. With most of the patients it was not possible to discover evidence of association with other cases, and instances of family contagion were observed among the members of only five families, in which side by side with typical examples of the disease there were abortive forms unaccompanied by paralysis. With regard to the clinical features, he said that some patients at the outset presented signs of meningitis and were treated by intraspinal injections. The contagiousness of this form of poliomyelitis varied with the epidemics, being sometimes very marked and sometimes only slight. In conjunction with M. Levaditi, M. Netter had been able to prove that the serum of patients who had suffered from infantile paralysis possessed neutralising properties with respect to the virus of poliomyelitis. These properties furnished evidence of the identity of epidemic and sporadic infantile paralysis; they were found in the blood of patients in whom the disease assumed the above-mentioned abortive forms.

Antirabic Vaccinations.

M. Jules Viala, *préparateur* in the antirabic department of the Pasteur Institute, has published the statistics of the antirabic vaccinations performed during the year 1909. Among the 467 persons who received this treatment there were two deaths from rabies, one of these patients being a woman in whom the disease declared itself during the treatment. This case ought obviously to be deducted in computing the mortality, which would then work out at the extremely low rate of 0·21 per cent.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Political Parties and Public Health Legislation.

THE Parliamentary Committee for the preliminary consideration of the proposed Infectious Diseases Act (Seuchengesetz) was on the point of completing its task when powerful political influence was suddenly exerted in opposition to some of its most important recommendations, such as the passing of special laws against tuberculosis and syphilis and the introduction of a Bill to make vaccination compulsory. The objections came from the Clerical party, which has its chief supporters amongst the peasant population, the members of this party declaring that the subject was so important that it must be referred to the population before they could vote either for or against it. There is a widespread feeling that the hostility of the Clerical party to the proposed legislation is really prompted by the fear of the expense which the rural population would incur in consequence of it. Country people do not readily understand that sanitary improvements must cost money. It now remains to be seen whether the Government will allow the public health to be endangered by the obstinacy of a political group which has little if any knowledge of the question at issue, and whether the principle of individual liberty will receive more consideration in this respect than it does in connexion with military conscription, with the imposition of rates and taxes, and with compulsory education.

A Remarkable Teratoma.

At a recent meeting of the Gesellschaft der Aerzte in Vienna, Dr. von Khautz showed an infant of nine months who had been brought to a hospital with a history of laborious breathing and an increasing swelling in the jugular notch. A provisional diagnosis of retrosternal struma was made and an operation was performed. The tumour, which was removed without much difficulty, was encapsulated, with a few adhesions binding it down to the thyroid gland. A section of the tumour showed the presence of several small cysts filled with a milky fluid of a kind not usually seen in colloid degeneration of the thyroid gland. Microscopic examination showed the presence of several kinds of tissue which had nothing in common with the gland. The tissues belonged mostly to the central nervous system; numerous cysts and glandular tubuli containing all sorts of epithelium were also found, as well as portions of muscular fibre and cartilage. One spot showed the presence of a cavity lined with intensely pigmented cells—an ocular rudiment such as has been described several times in similar cases. The diagnosis had therefore to be changed to one of teratoma.

The Treatment of Congenital Umbilical Hernia.

The comparative rarity of the herniæ of the umbilical cord justifies the making of an attempt to collect details of as many as possible with a view of comparing the conservative with the surgical method of treating them. In a paper read before the Medical Society Dr. von Haberer discussed this question, also showing an infant on whom he had operated for this condition 17 hours after birth. He said that at the present time surgeons seemed to prefer reposition without operation if the hernia could be replaced totally and if there were no retrogressive changes. In cases of partial irreducibility, or if gangrene of the sac or its contents threatened, there was no alternative to operation. In Dr. von Haberer's case, as well as in the majority of those reported by others, such as Breus, Felsenreich, and Finsterer, the operation revealed more or less extensive adhesions between the contents of the sac with each other or with the sac itself; in the circumstances conservative procedures would have had a fatal result. The infant shown by Dr. von Haberer, although otherwise normally developed, had a hernia of the size of an apple extending into the umbilical cord. Reposition was tried but was not wholly possible. This and a suspicion of gangrene aroused by some discolouration of the cord prompted him to operate. The sac contained much of the jejunum, the cæcum, and the ascending and transverse colon, and the mesentery of the entire colon was firmly adherent to the sac. The child made a good recovery. Dr. von Haberer said that infants who were not operated on might survive, even after gangrene of the covering tissue of the hernia, but they suffered severely from disturbances of nutrition. Surgical interference was therefore always advisable.

The Late Professor Zuckerkandl.

The late Professor Emil Zuckerkandl, who occupied the chair of normal anatomy in the University of Vienna for some 20 years, and whose obituary record recently appeared in THE LANCET, was an excellent teacher, being a fluent speaker in the lecture room and an unwearied worker amidst his students in the dissecting rooms. Fond of the fine arts, he used to point out the connexions between the anatomist and the painter and sculptor. His anatomical researches have no doubt prompted such men as Hajek and Alexander to continue in his steps as regards their specialty. Zuckerkandl's successor in the chair of anatomy is not yet nominated. At present Professor Tandler, the first assistant of the deceased professor and the most prominent of his pupils, is carrying on the work of teaching the students.

June 20th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the first week in May show 13,076 deaths for all India and Burma as compared with 15,466 deaths in the preceding week. The figures for the various provincial areas are: In the Punjab, 7350; Rajputana and Ajmer Merwara, 2789; the United Provinces, 1850; Bombay Presidency, 474; Bengal Presidency, 317; Burma, 188; the Central Provinces and Berar, 50; Madras Presidency, 58. The North-West Frontier Province and Baluchistan record no fatal cases, but Kashmir reports 39 deaths from Jammu for the two weeks ending on May 7th. In the Punjab the worst affected areas are the Amritsar district with 1738 deaths and Patiala State with a mortality of 1367. More than half the mortality in Rajputana and Ajmer Merwara occurred at Jaipur which returned 1521 deaths for the period comprising the latter half of March. The plague mortality in the United Provinces was highest in the Muttra district which had 353 deaths.

Small-pox and Cholera in the Pilgrimage.

For years the pilgrim traffic from India to Mecca has been a great trial to the public health authorities in the city of Bombáy, and much has been written and said on the subject of the introduction of small-pox and cholera into the city through it. At last the Government has issued a notification of advice to intending pilgrims in accordance with the following suggestions of the Commissioner of Police:—

Notification to Intending Pilgrims in Other Provinces regarding Passage Rates to Jeddah, and the Desirability of Getting Themselves Vaccinated before they start for Bombay.

The large influx of pilgrims into Bombay within a short time, is ascribed, by the Protector of Pilgrims, to reports regarding cheap passages to Jeddah, spread by Bengali Mahomedans from Arabia. To prevent a recurrence of this the Commissioner of Police suggests that the authorities in Bengal and Upper India should be asked to publish notifications urging those resident within their jurisdiction to give no credence to information circulated by irresponsible persons from the Hedjaz, and advising them to apply direct for information to the Protector of Pilgrims in Bombay. In view of the efforts being made to induce pilgrims to submit themselves to vaccination before embarkation, the Commissioner of Police further suggests that the notifications above referred to might also impress upon those intending to perform the Haj, the great desirability of getting themselves revaccinated before leaving their homes for Bombay, the local authorities being asked at the same time to endeavour to popularise the revaccination of intending pilgrims in the villages and towns, and to grant vaccination certificates to those who submit to the operation before departure for Bombay. The suggestions made by the Commissioner of Police should be communicated to the Government of India, who should be requested to address all local governments and administrations with a view to effect being given to them.

From October to April 21,000 pilgrims pass through Bombay on their way to Jeddah, and return in February, March, and April, as many as 9000 being in the city at one time. Bombay is a very crowded city, and the influx of 9000 pilgrims from all parts of the East, is a great strain on the authorities connected with public health administration. 17,000 of these pilgrims come from Burma, the remainder from Ceylon, Arabia, Africa, Afghanistan, China, Egypt, French India, Java, Persia, Russia, Turkey, and Thibet. The majority of them are of the poorest class, some are absolutely destitute, and many never return to their country. Small-pox and cholera are practically endemic in Mecca and Jeddah, and the returning pilgrims suffer accordingly. Certain precautions are taken in Bombay towards disinfecting the kit of the pilgrims going and returning, and at Perim infected steamers are disinfected, but many cases of small-pox occur during the return voyage, and pilgrims arrive in Bombay with the disease developed or in the incubating stage. Those suffering from the disease are taken to the municipal infectious diseases hospitals, their kit and the ship are disinfected, and the remaining pilgrims are allowed to land and disperse. Many fall sick and develop the disease while in the city, others develop it on their way back to their native place. It is to prevent this that measures are required, but it is to be feared that the notification above referred to will have little effect. Every person leaving Bombay for Europe is medically inspected for plague, and every possible precaution is taken to prevent the introduction of this disease into Europe. The Venice Convention and the Paris Convention have made elaborate rules for this, but what precaution is there for India? Every year hundreds of cases of small-pox are imported into Bombay. On the arrival of a pilgrim steamer with 800 or 900 pilgrims on board, information is sent to the health department of the city by the port health officer, and if small-pox or cholera exist arrangements are made to remove the cases to the municipal infectious diseases hospital, and the companions of the infected pilgrims are offered vaccination. Male and female vaccinators wait at the dock for the arrival of the steamers to persuade the pilgrims to be vaccinated, but with very slight success. The health department has, however, been agitating for strict measures, and until some such measures are enforced Bombay will continue to suffer. What would be done if Paris, Berlin, or Constantinople became the Mecca

and the faithful decided to proceed there in thousands under similar conditions? This is as much an international health question as plague or cholera, and if the Turkish Government issued a notification that pilgrims should be vaccinated in Bombay or their own country before being allowed to land at Jeddah or proceed to Mecca the result would be of immense importance to India generally and the city of Bombay particularly, as well as reducing the distress and discomfort of the pilgrims themselves.

Measures against Cholera.

The Government of Bombay has issued instructions as to the measures which should be adopted to prevent the spread of cholera among the various communities under its control. The notices, which are printed in English, Mahrathi, Gujrathi, Sindhi, and Canarese, explain the causation of the disease, advise strict cleanliness, and mention the various prophylactic precautions which may be taken.

Permanganate of Potash and Snake-bites.

Some confusion has arisen as to the meaning of the statement issued by the Sanitary Commissioner with the Government of India with regard to the treatment of snake-bites. In this statement reference is made to the danger of intravenous injection of permanganate of potash, and many laymen have understood this to mean that the local use of the drug is dangerous. In a letter to the Calcutta papers Major Leonard Rogers, I.M.S., who, with Sir Lauder Brunton, has advised the medical authorities on this subject, has cleared up the confusion, and has stated that the notice issued by the Sanitary Commissioner does not in any way refer to the well-known treatment of snakes-bites by local applications of permanganate of potash.

May 15th.

Obituary.

SAMUEL BUCKLEY, M.D. LOND., F.R.C.S. ENG., M.R.C.P. LOND., L.S.A.

THE death of Dr. Samuel Buckley of Bury Old-road, Manchester, on May 30th, removes a well-known medical figure from Manchester and its neighbourhood. His qualifications date back to 1868 when he passed "the College and the Hall"; he became F.R.C.S. by examination in 1873, M.D. Lond. in 1885, and M.R.C.P. Lond. in 1894. From 1870 to 1872 he was resident medical officer (medical and fever wards), Manchester Royal Infirmary, and his ability and devotion to duty are still remembered by one who knew him well. He was an ex-president of most of the medical societies of Manchester and of the North of England Obstetrical and Gynæcological Society, &c. He contributed occasional papers to the medical journals from 1885 to 1900, but chiefly to the North of England Obstetrical and Gynæcological Society's Transactions. He had been honorary physician to the Manchester Northern Hospital for Diseases of Women and Children for many years, and at the time of his death was consulting physician to the institution, one in which he always took a great interest. In a notice of his death in a local paper we read that, "Personally Dr. Buckley was a man of quiet, genial temperament and high-bred courtesy, which made it a real pleasure and charm to hold converse with him." His chief recreation was fishing, and the writer well remembers one pleasant fishing holiday spent in the West of Ireland when Dr. Buckley was an ever-genial member of the party. His death at the comparatively early age of 64 is a great loss to Manchester.

THOMAS EDWARD SMYTH, B.A., M.D., B.CH. DUB.,

HONORARY SURGEON TO THE TAVISTOCK COTTAGE HOSPITAL.

Dr. Thomas Edward Smyth, who died at his residence, Abbey House, Tavistock, Devon, on June 8th, had undergone an operation for appendicitis about two weeks previously. The deceased, who was in his forty-seventh year, was the younger son of the late Mr. George Smyth of Pembroke-road, Dublin, and was educated at Trinity College, Dublin. He graduated B.A., M.B., B.Ch., and four years later obtained the M.D. degree. After holding resident appointments at the Royal City of Dublin Hospital he was appointed Government medical officer at Campbelltown, New South Wales. While there he was surgeon-lieutenant in the New South Wales Mounted Rifles. Dr. Smyth left Australia in 1886 and came to Tavistock, succeeding to the practice of the late Dr. Swale. Dr. Smyth was a member of the honorary staff of the Tavistock Cottage Hospital, and took a great deal of active interest in the welfare of that institution. He was also medical officer to Kelly College, Tavistock, and to the post-office. He was extremely popular at Tavistock and much sympathy in felt there for his widow and son.

JAMES STARTIN, M.R.C.S. ENG.

THE death of Mr. James Startin in his fifty-ninth year occurred on June 2nd. He was born in 1851, and entered St. Thomas's Hospital as a student in 1870. Six years later he became a Member of the Royal College of Surgeons of England, and from the beginning of his career manifested an interest in dermatology. He was the inventor of several minor instruments for use in connexion with diseases of the skin, and amongst his works are "A Pharmacopœia for Diseases of the Skin," and "Parasitic Diseases of the Skin." He published many lectures also on the treatment of lupus and other skin diseases, amongst which is one entitled "X Rays in Lupus and Rodent Ulcer," which appeared in our columns. Mr. Startin was Vice-President of the Windsor and District Medical Society, and Fellow of the Medical Society of London and of the Hunterian Society. He was also senior surgeon and lecturer to the London Skin Hospital, Fitzroy-square.

GEORGE OLDHAM SIDDALL, M.R.C.S. ENG., L.S.A.

Mr. George Oldham Siddall died at his residence in Plymouth on June 1st in his seventy-sixth year. He was born at Alfreton, Derbyshire. He studied medicine at St. Thomas's Hospital and while still a student volunteered for medical service in the Baltic during the war with Russia. He served on H.M.S. *Arrogance* in 1855, under Captain (afterwards Admiral) Yelverton. During the campaign he saw some fighting, being present in the action at Viborg, and at the bombardment of Sweaborg. At the termination of the war Mr. Siddall returned to England, where he completed his medical curriculum, taking the L.S.A. in 1856 and becoming a Member of the Royal College of Surgeons of England in the following year. He then commenced to practise at Alfreton, where he soon established a considerable connexion. He retired about 16 years ago and went to Plymouth, where he became proprietor of the Lockyer Hotel. He was extremely popular at the "Three Towns," especially amongst the naval and military officers. He gave up his connexion with the hotel in 1909. Mr. Siddall was a good sportsman and a constant follower of the local hounds. He will be greatly missed in Plymouth, and much sympathy is felt there for his widow and family.

THE LATE DR. A. J. SHARP.—We regret to have stated that Dr. A. J. Sharp, whose death, following upon a post-mortem infection, we announced last week, had suffered for more than six years from the sad accident. We should have said "six and a half months."—ED. L.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* The honorary degree of Doctor of Medicine is to be conferred on Dr. E. A. Schäfer, Professor of Physiology in the University of Edinburgh.—*Giessen:* Dr. Leutert, Professor of Otology, has announced his intention of resigning because the authorities have not been able to grant sufficient funds to build a new otological clinic, which he looks upon as absolutely essential.—*Heidelberg:* Dr. Grafe has been recognised as *privat-docent* of Medicine.—*Königsberg:* Dr. Lippmann and Dr. Borchardt, Assistants in the Medical Clinic of the University, have been recognised as *privat-docenten* of Medicine, and Dr. Bürgers as *privat-docent* of Hygiene.—*Lemberg:* Dr. Kasimir Orzechowski has been recognised as *privat-docent* of Neuro-pathology.—*Rheims:* Dr. Téchoueyres has been appointed Professor of Histology.—*Tübingen:* Dr. von Bruns, Professor of Surgery, having attained the age of 64 years, proposes

to retire at the end of the current session.—*Würzburg:* Lectures will be given by Dr. Rosenberger, Professor of Surgery, on Accidental Injuries, and by Dr. Reichardt, *privat-docent* of Psychiatry, on Social Legislation and Expert Evidence. Dr. K. Hess, Professor of Ophthalmology, who had been invited to migrate to Heidelberg to succeed Professor Th. Leber, has decided to remain in Würzburg. The charge of the Pathological Institute and the pathological instruction has been given during the vacancy of the chair (due to Dr. M. Borst's migration to Munich as von Böllinger's successor) to Dr. A. Schmincke, *privat-docent.*—*Zürich:* Dr. Karl Henschen has been recognised as *privat-docent* of Surgery.

THE Paris Academy of Medicine has elected Dr. Guilloz of Nancy and Dr. Florence of Lyons as corresponding members.

SALFORD AND ITS BUILDING BY-LAWS.—A rather serious criticism is just now being made as to the building by-laws of Salford, which are more antique than those of Manchester and much less thorough than those of Levenshulme, a suburb which has recently become a part of Manchester. It cannot be denied that in some of its parts Salford abounds in slums, and as slums minister to the deterioration of physique, both directly and indirectly, it is desirable that as rapidly as possible they should be improved away. As regards building by-laws Levenshulme stands on a higher level than Manchester, and when it was amalgamated with Manchester a special clause in the Act of Parliament guaranteed Levenshulme a continuance of its by-laws. A few instances will show their superiority. The minimum area for yards of domestic houses is in Levenshulme 400 superficial feet, in Manchester 250, and in Salford 150. In the first again and in the second the foundations of domestic houses are to be covered with a layer of asphalt or concrete, while in Salford there is no requirement, and houses may and are built on what is euphemistically called "the virgin soil." In Levenshulme staircases must not be steeper than 45°, they must have a window opening to the external air, also a hand-rail. Manchester has much the same rules, but in Salford the builder may make the staircases as steep as he likes and without ventilation or hand-rail. In Manchester and Levenshulme one living- and one sleeping-room must have at least 144 superficial feet, but in Salford there is no minimum space given, and in some houses rooms are only 6 feet by 8 feet. It is only about two years, however, since Manchester could claim superiority over Salford, but some new by-laws were then adopted, and now it may be hoped that she and Salford also will strive to attain to the position of Levenshulme.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Salary of the President of the Local Government Board.

THE House of Commons, in assenting to an item in the estimates which provided that the salary of Mr. BURNS, as President of the Local Government Board, should be £5000 per annum, has sanctioned the arrangement whereby this department has its status "levelled up" to that of the departments in charge of Secretaries of State. The PRIME MINISTER, in recommending the arrangement to the House, made mention of the numerous duties which recent legislation had imposed on the Local Government Board. The President's salary was formerly £2000 a year.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 15TH.

Colour-vision Tests.

Sir WILLIAM COLLINS asked the President of the Board of Trade whether Dr. Edridge-Green was employed as expert adviser to the Board in regard to sight tests; and, if so, when he ceased to act in that capacity and on what grounds; whether he was satisfied with the method of testing for colour-blindness at present employed by the Board; on whose advice it was adopted; and whether the adoption of an alternative system was under consideration.—Mr. BUXTON wrote in reply: Dr. Edridge-Green was appointed a member of the International Code of Signals Committee in May, 1889, when the question of colour-blindness was referred to. In view of the report of the Royal Society's Committee on Colour Vision, issued in April, 1892 the subject was withdrawn from the consideration of the Signals Committee, of which Dr. Edridge-Green then ceased to be a member. The present system of tests is based on the Report of the Royal Society's Committee.

THURSDAY, JUNE 16TH.

Deaths from Tuberculosis in Ireland.

Mr. STEPHEN GWYNN asked the Chief Secretary to the Lord Lieutenant of Ireland whether any returns of the Registrar-General showed any change in the proportion of deaths in Ireland due to tuberculosis.—Mr. BIRRELL replied: The Registrar-General's returns show that the total number of deaths from all forms of tuberculosis in Ireland have decreased from 11,679 in 1907 to 11,293 in 1908, and to 10,594 in 1909. The marked decrease in the number of deaths from tuberculosis is very gratifying and must prove a great encouragement to those who for some years past have been engaged in a strenuous effort to check and extirpate the disease.

Mr. MOONEY: May I ask whether it is a fact that during the past 12 months the Registrar-General has adopted a completely different method of classification in the mortality returns, and whether that accounts for a considerable amount of the decrease?

Mr. BIRRELL: I do not want to exaggerate or minimise the decrease. The figures are as I have given showing a decrease.

Mr. MOONEY: Is it not due to the new method of classification?

Mr. BIRRELL: There has been some change, but whether it would have the effect suggested by the honourable Member I am not in a position to say.

Woolwich Municipal Milk Depôt.

Mr. RAMSAY MACDONALD asked the President of the Local Government Board whether he had received a report from the Woolwich borough council respecting the proposed abolition of the municipal milk depôt for supplying specially prepared milk to infants, which was established in pursuance of a private Bill affecting the borough; and whether he would call for a report on the subject from the medical officer of health of Woolwich and communicate with the borough council on the subject.—Mr. BURNS answered: I am communicating with the corporation in reference to this matter.

The Medical Prison Commissioner.

Dr. HILLIER asked the Secretary of State for the Home Department whether it was his intention to appoint as a Prison Commissioner a medical man skilled in mental disease.—Mr. CHURCHILL said in reply: Dr. Donkin, who was for several years one of the Prison Commissioners, on his retirement in February last from the post of commissioner was retained in the position of medical adviser to the Prison Board, and in that position has a voice at the meetings of the Board, and exercises his medical functions as fully as he did in his former capacity. He is specially skilled in all questions of mental disease, and his expert knowledge has been of great service both to the prison administration and to the Royal Commission on the Feeble-Minded, of which he was a member. So long as he retains his present post the appointment of a medical commissioner is not considered necessary.

Dr. HILLIER: Is the right honourable gentleman aware that the present Prime Minister, when this question was raised some years ago, very strongly urged that there should be a competent qualified medical man placed amongst the Prison Commissioners on the Board, and that the Board should not merely be dependent on outside medical advice?

Mr. CHURCHILL: This has already formed the subject of a debate in this House, and I could not attempt to reply to the arguments in answer to a question.

Dr. HILLIER: Is the right honourable gentleman aware that the Under Secretary of State for the Home Department in the course of the debate clearly intimated that it was quite probable that a further appointment would be made to the Board?

The SPEAKER: Order, Order! That does not arise out of the question.

Deaths in County Asylums.

Mr. SNOWDEN asked the Secretary of State for the Home Department whether he was aware that patients chargeable to Poor-law unions who died in the county asylums were described as pauper patients in the notice of death sent out from the asylums, and, as such description was not only unnecessary but very objectionable and hurtful to the feelings of the relatives at a time of bereavement, would he at once take steps to stop the practice.—Mr. CHURCHILL replied: I am in communication with the Commissioners in Lunacy on this matter.

Children in Workhouse Infirmaries.

Mr. ORMSBY-GORE asked the President of the Local Government Board to state the number of children who, at the date of the last return, were being maintained in workhouses and workhouse infirmaries respectively, differentiating between those over and those under three years of age.—Mr. BURNS (by written answer) replied: The latest returns—viz., those for Jan. 1st, 1910, show that the number of children in separate Poor law infirmaries in England and Wales was 7128, whilst the number in workhouse wards (including infirm wards) was 17,047. The returns do not show how many of these children were over three years of age and how many were under that age; but they show that of the total number of children in all Poor-law establishments 8914 were under the age of three. The majority of these would necessarily be in workhouses and workhouse infirmaries, and could not well be separated from their mothers.

Colour-vision Tests.

Sir WILLIAM COLLINS asked the President of the Board of Trade whether, in view of the considerable proportion of cases in which appeals against the decision of the Board of Trade's sight tests with Holmgren's wools resulted in reversal of the previous decision, it was proposed to institute a new system of sight tests to supersede that recommended by the Royal Society in 1892.—Mr. BUXTON wrote in reply: The important question to which my honourable friend refers is engaging my careful attention, and I hope shortly to make an announcement with regard to it.

FRIDAY, JUNE 17TH.

Vaccination.

On the vote for the salaries and expenses of the Local Government Board,

Mr. CHAPLIN raised the question of vaccination, in regard to which he was afraid the action of the President had rather retrograded. He mentioned that at the present time complaints were extremely common on the part of vaccination officers. These complaints were raised on the ground that the officers had got more to do since the passing of the Act of 1907, and they received less for their work. He went on to refer to the legislation of 1898 and 1907 and to its effect on the conscientious objector. In 1899 the exemptions from vaccination were 32,000, and in the year when the present Government came into office they were 52,000. In the year 1907 they were 57,000, and that was the year of the passing of the Act by which the statutory declaration was substituted

for the necessity of going before a magistrate for the purpose of getting exemption. What were the exemptions in the following years? They went up to 162,800 in 1908 and to 190,000 in 1909; that was to say, they went up from a percentage of 4·6 in 1905 to 20·8 in 1909. That happened in two years after the passing of the Act. If exemptions proceeded in the future with anything like the rapidity which they had recently done, vaccination would be in a dangerous position in this country. Everyone must see that the position was one of a grave and serious character. When hon. Members were confronted with results like these in so very short a time after the passing of an Act to amend the Act of 1898, he thought that the right honourable gentleman would allow that he (Mr. Chaplin) was, at all events, justified in taking this early opportunity of pointing to some of the consequences which had followed. He hoped that the President of the Local Government Board would take into his most serious consideration the question whether steps ought not to be taken to discourage this enormous increase in the exemptions from vaccination, which, if they continued at their present rate, must constitute a great danger to the country.

Mr. BURNS (the President of the Local Government Board) said, in reply, that he would deal with the complaint of the vaccination officers before coming to the question of vaccination itself. There were 1420 vaccination officers in England and Wales and they were all paid by fees. 400 gave their whole time to the work and 1020 held other appointments, such as relieving officers or registrars of births, marriages, and deaths. Honourable Members should bear that in mind when considering the question of their total remuneration. The fees paid to them were paid and fixed by consent of the Local Government Board. Some people talked about the minimum fee of 3*d*. being adhered to and thought that 9*d*. was paid for every successful vaccination alone. In many cases where the population was dense the guardians thought that the minimum fees of 3*d*. and 9*d*. respectively yielded sufficient remuneration. Where the population was not so dense the 3*d*. fee became 6*d*., and the 9*d*. in the case of successful vaccination became a fee of 1*s*. 6*d*. or 2*s*. 3*d*. and the average remuneration of these gentlemen for this work was very often from £150 to £200 and in some cases £300. He found that since the Act of 1907 was passed, when he only carried one step further the principle of helping the conscientious objector, the exemptions had increased from 57,675, or 6·2 per cent., to 190,000, or 20·8 per cent. The exemptions had in some cases caused a diminution of income to some of the officers. He found that out of the 1420 vaccination officers, it was alleged that 437 had sustained a loss; but out of that number 217, or nearly a half, had been paid by their boards of guardians a gratuity to make good the loss, and this had been done with the consent of the Local Government Board. In the remaining cases vaccination officers had not always seen their way to apply for compensation, which was not his fault, or else the guardians had declined to pay gratuities. These two classes had to be met. Various suggestions had been made to meet these cases, but a number of them he could not consider. However, he was prepared to receive both from the vaccination officers and from the guardians a statement of their grievances as applied to each individual case where a reduction had been sustained, and he was prepared to meet them as fairly as in the interests of the public he had a right to meet them. That, he thought, was sympathetic and fair. The right honourable gentleman had suggested that the increase in the number of exemptions was a retrograde step and one from which he feared serious consequences. That, of course, was a matter of opinion, and upon it the House was rather sharply divided. So far as he could gather, although the exemptions had increased from 6 to 20 per cent. between 1907 and 1909, he was glad to inform the House that taking London, he saw from the report of the Local Government Board that in 1908, a year after the passing of the Act when the exemptions were rapidly increasing, there was not a single case of small-pox admitted in the small-pox hospitals of the Metropolitan Asylums Board.

Dr. HILLIER: A very happy coincidence.

Mr. BURNS: And the happy coincidence has continued since 1909. He did not share the alarming fears and suggestions of some people that one of the results of the exemptions under the Act of 1907 would be a serious increase of small-pox cases, and there was no reason to assume that the Act would have that effect. He thought that both the vaccinator and the anti-vaccinator had not sufficiently given credit to the effect on the education of the individual and of the improvement in domestic and public sanitation. He was positively convinced, taking a view of the whole situation, that neither the views of the one nor the hopes of the other had been justified by the last two years. It was with peculiar pleasure that he was able to say that there were no immediate signs or even prospects of the alarms and fears of the honourable Members with regard to vaccination being proved by facts and results.

MONDAY, JUNE 20TH.

Certifying Surgeons.

Mr. WEDGWOOD asked the Secretary of State for the Home Department whether he contemplated taking any steps to prevent the official certifying surgeons acting privately for trade unions or insurance companies in any capacity wherein fees were paid for medical decisions or reports.—Mr. CHURCHILL answered: It would not be possible to lay down any general rule on the subject, because in industrial districts it is often difficult to find a well-qualified medical man who does not hold some appointment in connexion with employers or associations of workpeople. The consideration, however, is borne in mind in making appointments, and the department is always prepared to inquire into any case of grievance that may be brought to its notice. I may add that an appeal lies from decisions of a certifying surgeon under the Workmen's Compensation Act to the medical referee appointed under that Act.

Infectious Hospitals.

Major ADAM asked the President of the Local Government Board whether he could state the number of infectious hospitals provided by the various local sanitary authorities in England and Wales, their cost for erection and maintenance, and the number of patients admitted over a convenient period of years; and whether, in view of the diversity of the skilled and medical experience which existed on the subject and the cost to the ratepayers which was involved, he would cause an inquiry to be made into the whole question of the usefulness of infectious hospitals, other than small-pox hospitals, as a means of preventing the spread of disease, and generally, in view of the extended experience which now existed on the subject, into the advantages or disadvantages which might be found to attend their use.—Mr. BURNS replied: I am not at present in possession of complete information on the points mentioned in the first part of the question. I may say, however, that by the general order which will very shortly be issued in pursuance of Subsection 2 of Section 68 of the Housing, Town Planning, &c., Act of last session the county medical officer of health will be required to inquire into, and report upon, the hospital accommodation in each county and upon any need for the provision of further accommodation. As regards the second part of the question I am advised that there can be no doubt as to the utility of isolation hospitals in the prevention of the spread of infectious diseases when conjoined with good administration in regard to the other means necessary to prevent the spread of infection, among which the careful search for overlooked or non-notified cases of the same disease bears an important part.

TUESDAY, JUNE 21ST.

Postmen and Infection.

Captain FABER asked the Postmaster-General what precautions, if any, were taken concerning postmen going on duty who had members of their families ill from contagious disease.—Mr. H. SAMUEL replied: In the case of certain specified diseases a postman is placed off duty immediately, and is not allowed to resume until instructions have been received from the chief medical officer to the Post Office. In the case of other diseases the postman remains on duty, but the case is at once reported to the chief medical officer, who advises whether it is necessary that the employee concerned should absent himself. Absence from duty on full pay is insisted on if there is considered to be any risk of conveying the infection, whether to the local post-office staff or to the public generally.

The Census and the Birth-rate.

During the consideration of the Census Bill in Committee,

Mr. RAWLINSON moved an amendment to omit from the census forms the inquiry as to the number of children born of the marriage. He feared that the inquiry would be regarded as inquisitorial.

Mr. BURNS, in resisting the amendment, said that he did not see how the inquiry could be regarded as inquisitorial. It was only confined to the number of children of an existing marriage. The reason why this question was being included was that nearly all the countries of the world were confronted with a very remarkable diminution of the birth-rate. The marriage-rate was stationary or showed only a slight diminution. To medical men and others interested in the matter of the birth-rate the information to be derived from such an inquiry was valuable as showing the fertility of marriages. He was told of one professional occupation in which married women were employed almost as extensively as married men, where it was ascertained by a local authority that although the families from which the woman and her husband spring numbered on an average five or six, the average number of their own family was only one. That threw an interesting sidelight upon the employment of women. Such information as the census might afford in this respect might also throw light on infant mortality and on the subject of feeble-minded children. The amendment was rejected by 151 votes to 61.

WEDNESDAY, JUNE 22ND.

The Medical Inspection of Schools.

Mr. CHARLES BATHURST asked the President of the Board of Education whether the Board had now received reports from every county in England and Wales showing the results for a complete year of the medical inspection of the children in the elementary schools; whether such reports disclosed the fact that over 40 per cent. of such children were suffering from some physical defect and that over 20 per cent. required, and should receive, some medical treatment; and whether, both in the interests of the national physique and to avoid the serious waste of public money consequent upon the attempt to educate children who were more or less physically incapable of receiving education, the Board proposed to take any, and, if so, what, steps to remedy the condition disclosed by the above reports.—Mr. RUNCIMAN said in reply: With reference to the first part of the question, the Board has received reports for the year 1909 from about two-thirds of the local education authorities concerned. It is not possible to state the facts revealed by the reports which have been received in the form suggested in the second part of the question. The report of the chief medical inspector based upon the reports received from the local education authorities will be prepared in due course, and will deal fully with the conclustons which can be reasonably drawn from the results of the medical inspection in the year in question. As regards the third part of the question, the honourable Member is no doubt aware that the local education authorities have the power, with the approval of the Board of Education, under Section 13 (1) (b) of the Education (Administrative) Provisions Act, 1907, to make arrangements for attending to the health and physical condition of children educated in public elementary schools. This power is being exercised in various ways by many authorities.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BYRES, W. J., M.D.Aberd., has been appointed Interim Visiting Medical Officer of the Oldmill Poorhouse, Aberdeen.

COLLINS, J. RUPERT, M.D.Dub., has been appointed Honorary Physician to the Cheltenham General Hospital.

DILLON, T. F., M.B., B.S.R.U.I., has been appointed Hospital Surgeon and Principal Medical Officer by the Committee of the Ebbw Vale Works.

EDGAR, N., has been appointed Dental House Surgeon at Guy's Hospital.

HOOD, BASIL, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Superintendent of Marylebone Infirmary.

HUNTER, J., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Linlithgow District of the county of Linlithgow.

LAWTON, J. J., L.R.C.P. & S Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Midleton District of the county of Cork.

MAGOWAN, S. M., M.B., M.S.R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Glenarm District of the county of Antrim.

ORMEROD, E. W., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Southam District of the county of Warwick.

OULTON, E. V., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed an Assistant Inspector of the First Class and Surgeon to the Ophthalmic Hospitals of Egypt.

REYNOLDS, A. J., has been appointed Dental House Surgeon at Guy's Hospital.

SAUL, A. L., has been appointed Dental House Surgeon at Guy's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN UNIVERSITY.—Examiners.

AYR COUNTY HOSPITAL.—Resident House Surgeon. Salary £70 per annum, with board and residence.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Special Clinical Assistants. Salary at rate of £100 a year. Also Dental Surgeon Also House Surgeon for six months. Salary at rate of £20 per annum, with board and residence.

BIRMINGHAM, CITY FEVER HOSPITAL, Lodge-road.—Medical Superintendent, unmarried. Salary £250 per annum, with board and residence.

BRADFORD, ROYAL EYE AND EAR HOSPITAL.—Resident Officer (female). Salary £80 per annum, with board and laundry.

BRIGHTON, SUSSEX COUNTY HOSPITAL. Resident Medical Officer for six weeks. Salary 18 guineas, with apartments, board, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—Senior and Junior House Surgeon for six months. Salaries £80 and £70 per annum respectively.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon; also House Surgeon for Ophthalmic and Ear and Throat Departments, each for six months. Salary £30, with board, residence, and laundry.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary £50 per annum, with board and residence.

CLAYBURY, LONDON COUNTY ASYLUM, Woodford Bridge, Essex.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance. Also Honorary Aural Surgeon.

DONCASTER ROYAL INFIRMARY AND DISPENSARY.—House Surgeon, unmarried. Salary £125 per annum, with board and residence.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—House Physician. Salary at rate of £60 per annum, with board, residence, and washing.

FRIMLEY, BROMPTON HOSPITAL SANATORIUM.—Assistant Resident Medical Officer. Salary £150 per annum, with board and residence.

GLASGOW MATERNITY AND WOMEN'S HOSPITAL.—Indoor House Surgeon for six months. Salary at rate of £50 per annum. Also Two Outdoor House Surgeons and Outdoor House Surgeon (female) to the West-end Branch, all for three months. Salaries at rate of £72 per annum.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HARTLEPOOL, HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HIGHBURY HILL HIGH SCHOOL FOR GIRLS.—Female Practitioner. Salary £50 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Radiographer. Salary 50 guineas per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician and House Surgeon, both unmarried, for six months. Salary in each case £30, with board, residence, and washing.

HULL, ROYAL INFIRMARY.—Casualty House Surgeon for six months. Salary at rate of £60 per annum, with board and lodging.

JARROW-ON-TYNE, PALMER MEMORIAL HOSPITAL.—House Surgeon, unmarried. Salary £ 50 per annum, with board and residence.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, and board.

KIRKBURTON, NEAR HUDDERSFIELD, STORTHES HALL ASYLUM.—Locum Tenens for two months. Salary 3 guineas per week, with board, lodging, and attendance.

LEEDS UNIVERSITY.—Demonstrator of Pathology. Salary £200 per annum.

MANCHESTER UNIVERSITY.—Junior Demonstrator in Physiology. Salary £100 per annum.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Honorary Surgeon. Also Pathologist and Registrar. Salary £75 per annum

NATIONAL SOCIETY FOR EPILEPTICS.—Visiting Physician (female) to the Chalfont Colony School. Salary £50 per annum.

NEWCASTLE, COUNTY WICKLOW, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND.—Senior Resident Medical Officer. Salary £300 per annum, with house accommodation.

NOTTINGHAM CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Surgeon and House Physician for six months. Salary in each case at rate of £80 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with board, lodging, washing, &c.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—Three Clinical Assistants.

ST. MARY'S HOSPITAL, London, W.—Resident Assistant Anæsthetist for six months. Salary at rate of £100 per annum, with board and residence.

SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, attendance, and rations.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician, unmarried. Salary £50 each per annum, with board, lodging, and washing. Also Casualty Officer. Salary £60 per annum.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, apartments, and washing.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging.

WEST BROMWICH DISTRICT HOSPITAL.—Assistant Resident House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL—House Physician.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Eskdale, in the county of Cumberland.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On June 13th, at Broad-street, Oxford, the wife of P. H. Adams, F.R.C.S., of a daughter.

FINLEY.—On June 14th, at West Malvern, the wife of Harry Finley, M.D. Lond., of a daughter.

LAING.—On June 17th, at Husbands Bosworth, Rugby, the wife of G. D. Laing, M.D., of a daughter.

MARRIAGES.

BOUSFIELD—EMERSON.—On June 15th, at St. Mary Abbot's Church, Kensington, Captain Leonard Bousfield, R.A.M.C., to Jenny Maude, only daughter of Sir William Emerson.

BRISTOW—WHITE.—On June 15th, at the Church of the Annunciation, Chislehurst, Walter Rowley Bristow, F.R.C.S., M.B., B.S., to Florence, daughter of James White, LL.D.

FOULDS—CHANCE.—On June 16th, at Great Alne Parish Church, Captain F. M. Foulds, R.A.M.C., to Stella Mabel, only daughter of Mr. and Mrs. Arthur Lucas Chance.

GIBBON—COOPER.—On June 11th, at Rathaspeck Church, Wexford, Captain T. H. Gibbon, R.A.M.C., to Elizabeth Mary, eldest daughter of Mr. H. Cooper, Drinagh, Wexford.

KENT—LLOYD.—On June 21st, at St. Bueno's Church, Berriew, Hugh Braund Kent, M.B., B.S. Lond., M.R.C.S., L.R.C.P., to Margaret Mary, second daughter of Mr. Edward Lloyd, of Berriew, Montgomery.

SMITH—DURSTON.—On June 14th, at All Saints' Church, Blackheath, Frank Wybourn Smith, M.R.C.S., L.R.C.P. Lond., Surgeon, R.N.V.R., to Winifred Florence, daughter of Engineer Vice-Admiral Sir John Durston, K.C.B.

DEATHS.

BOYD.—On June 16th, at 134, Harley-street, W., Florence Nightingale Boyd, M.D., wife of Stanley Boyd, F.R.C.S.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

GARDENING AS A HEALTH-CURE.

To the Editor of THE LANCET.

SIR,—As a member of the gardening profession, may I be allowed to enter a protest in connexion with Dr. Jane Walker's paper on the Industrial Treatment of Tuberculosis, read at the Women's Congress at the Japan-British Exhibition this month.

Dr. Jane Walker is reported as advocating gardening, and more particularly French gardening, to be carried on in connexion with market work by the patients in sanatoria for the treatment of consumption. One who is not a doctor must not, of course, trespass on medical ground, but I believe I am right in supposing that any great expenditure of physical strength should be carefully guarded against in treating a disease in which the patient is constantly losing tissue.

Now gardening is very hard work indeed, and of all branches French gardening probably puts the greatest strain on physical energy and endurance. Dr. Jane Walker mentions as drawbacks to the success of her idea—(1) costliness of the scheme; and (2) difficulty of obtaining a market. I would suggest that if the labour (which Dr. Jane Walker, with unconscious humour, further proposes shall be "graduated") is to be supplied by semi-invalids financial complications may fairly be anticipated.

Further, Sir, I submit that the increased practice of sending to be trained as professional gardeners not tuberculous sufferers alone, but girls and women who are handicapped with every type of delicacy, in the belief that an out-door occupation will be their best chance in life, is becoming a menace to the interests of all concerned. The presence of such women at our horticultural colleges upsets the balance of work, throws an unfair responsibility on the staff, endangers the health of the patients (I cannot class them otherwise), and brings discredit on our calling. People will very naturally refuse to apply for women gardeners when it is found that a large proportion are totally unfit to undertake the routine of manual work which forms the chief part of a gardener's life.

This abuse can only be rectified by insisting upon an absolute distinction between the invalid amateur gardener and the professional gardener possessed of normal health. By all means let the former play at gardening in his or her own home, or practise it in a special school or sanatorium where a sound man can be found for the enviable post of assistant (!) to wheel barrows, trench heavy ground, cut hedges, weed crops in hot weather, and so on, and where the patient can stop work as soon as fatigue or any other adverse condition prevails. But need I point out that such a state of things is only possible where it is not proposed to run a garden for profit?

One other point should be mentioned in this connexion—namely, that gardening seems usually to be regarded as a cure for all ills; and as a consequence, victims of melancholia, the neurasthenic and hysterical, the inebriate—in a word the mentally and morally unsound—are foisted upon us. Whether gardening may be good for these unfortunate people I am, of course, unqualified to judge, though I certainly have known the element of monotonous drudgery in gardening to prove a stumbling-block to hysterical and melancholy people through their inability to stick to one kind of work. But the injustice, as in the case of physical incapacity, lies in discounting the status both of the normal worker and of the work itself, as if gardening were only a proper occupation for the feeble-minded, instead of one which makes the greatest demands upon the intelligence and resource of its followers.

In urging these considerations, I do not wish to criticise any individual college or sanatorium, but merely to protest against an unsound principle. In so doing I believe that I shall have the support not only of professional gardeners of both sexes, but also of women who have proved this method of treating their health to be a failure. In the interests of both classes, may I not appeal to the medical profession for a more thorough inquiry into facts and conditions before they advocate the profession of gardening as a health-cure?

I am, Sir, yours faithfully,

West Hampstead, N.W. H. C.

THE FACTORY GIRLS' COUNTRY HOLIDAY FUND.

THE work of this Fund shows steady and continuous growth, and consequently there is urgent need of funds. In 1888 39 girls were sent away for a rest in the country, while in 1909 the number of girls who benefited by the Fund was 4870. As the report for the past year points out: "The work has been found to have a high educational value. By requiring the poor as far as possible to help themselves; by insisting that the girls must, wherever possible, put aside pennies in order themselves to contribute towards their expenses, the Fund has encouraged foresight, thrift, and self-reliance; by making it a condition of sending a girl away that she must provide herself with a decent and tidy outfit, it has taught many girls the importance and economy of tidiness, neatness, and 'a stitch in time.'" From the health point of view the need for a holiday in the country or at the seaside in the case of girls who are compelled to work in factories is obvious, and we cordially support the request of the committee of the Fund that subscriptions and donations should be sent in early in the year. The address of the society, which is entirely non-sectarian, is St. Peter's Rectory, Saffron-hill, London, E.C.

A CENSUS OF SPECTACLES.

To the Editor of THE LANCET.

SIR,—Next year (1911) the decennial census of the United Kingdom will take place, as we are being forewarned by numerous paragraphs appearing in the press. May I suggest that a question should be asked on every census form, "Do you wear eye-glasses or spectacles?" It seems to me from casual observations that we shall soon earn the title of "Bespectacled Britain," and in this respect shall race the Germans; but how a bespectacled race will control airships and "flying" motor-cars gives one "furiously to think." Of course, spectacles worn thus are aids to defective vision and not mere dust protectors like goggles. I observe it was stated in the House of Commons on June 14th that the officers and men serving in submarines did not have their eyesight affected in consequence. It might be though that the human eye will improve by travelling in airships until it becomes like the eye of the hawk or the eagle, or it may blind a few. However, putting aside such speculations, as the wearing of spectacles cannot be a matter for much secrecy, few persons would object to answer such a simple question, and it would afford a valuable index of the "eyesight of the nation."

I am, Sir, yours faithfully,

London, June 18th, 1910. MYOPE.

AN INDECENT MORTUARY.

THE absence of mortuary accommodation in the country districts and small towns is quite a frequent cause of complaint. The mortuary at the small town of Rye, in Sussex, came in for some severe criticism at an inquest which was held at the ancient borough on June 13th. But the severity of the criticism was not more than the case deserved. A juror in the first place called attention to the scanty covering of the body which they had just viewed. The reply was that all that could be found was a cloth. Then up spoke a medical man. The mortuary, he said, was without water or gas; it was objectionable and insanitary, and children could see the body from a crack in the window. No wonder the jury added a rider to their verdict calling the attention of the local authorities to the condition of the mortuary, asking them to make it sanitary and decent by the provision of water and light, and everything else which was essential for the convenience of those holding post-mortem examinations.

THE WOMEN'S HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—The results of our yearly appeals in the press have been of such immense value in the past that we trust you will once more allow us space in which to plead the cause of the Women's Holiday Fund. We helped over 1000 working women to get away from noise and gloom and toil for a week or two last year. They all paid what they could afford towards their expenses, but only a small part actually of the whole cost. Applications are now pouring in and many must be refused unless our receipts are greatly increased.

We are now setting apart a house for mothers and infants, specially supervised by a competent person. By this scheme we hope not only to prevent those in our other houses from being disturbed by children, but also that many valuable lessons in the management and feeding of young children may be learnt from the lady who is undertaking the task of supervision. This scheme entails some extra expense, and we are anxious that our numbers should not be reduced as a result of an experiment from which we hope much good will come. We shall therefore be more than ever grateful if those looking forward to a summer holiday will spare a few shillings for their less fortunate sisters who long to get away but cannot afford to pay for a holiday.

We are, Sir, yours faithfully,

A. F. LONDON.
H. L. STEPNEY.
FRANCIS M. WYNDHAM.
J. SCOTT LIDGETT.
HELEN A. POWNALL
(Chairman, Exec. Com. W.H.F.)

Subscriptions and donations will be gratefully acknowledged by the Hon. Treasurer, Mr. A. S. Daniell, Fairchildes, Warlingham, Surrey, or by Miss Crawford, Secretary, W.H.F., 76, Denison House, Vauxhall Bridge-road, S.W.

THE UNIVERSITY OF BRISTOL AND ACADEMIC COSTUME.

ON May 23rd the following regulations were issued from the University:—

Bachelors shall wear a black stuff gown of the Cambridge B.A. pattern. The gown of Bachelors of Medicine shall be of stuff or of silk. Masters shall wear a black stuff or silk gown of the Oxford M.A. pattern, save that the sleeves shall be ended with rounded corners and a slight concavity in the lower border without any nick in the side. Doctors in undress shall wear a black silk gown of the same shape as the Masters' gown, with a triangular area of black scroll-work in braid above each armhole. Doctors in full dress shall wear a scarlet cloth gown of the Oxford M.D. shape, save that the sleeves shall be entirely of cloth. The facing of the gown to a width of

3½ inches shall be in the colour proper to the degree as hereinafter prescribed. Graduates shall wear a square academic cap of the customary mortar-board pattern. The caps of Masters and Bachelors shall be covered with black cloth; the caps of Doctors with black velvet. The tassels shall in all cases be of black silk. Graduates shall wear hoods of the Cambridge pattern. The hoods of Bachelors shall be of stuff or of silk; those of Masters and Doctors of silk. Hoods shall in all cases be of a registered colour, which shall be called University red. Masters' hoods shall in all cases be lined throughout with white silk. Doctors' hoods shall be lined throughout with salmon-coloured silk, the same being used for the facing of the full-dress Doctors' gown.

From the commencement of the academic year 1910–11, undergraduates shall wear academic costume while in University precincts, such costume to be a black cap and gown of the customary pattern.

TOOTH-BRUSHES FOR WORKHOUSE CHILDREN.

No matter how small the instance may be, it is a wholesome sign to find a public body with children under its care making provision for the preservation of healthy mouths. It shows at least that all that has been said and written during the last year or two on the subject has not been in vain, while it suggests that publicity given to the decision of one body will lead to emulation in others, and thus in the near future there will be a considerable diminution in dental disease with a corresponding improvement in the general health of the people. The Midhurst board of guardians—one of the Sussex Poor-law unions—on June 13th decided to purchase half a gross of tooth-brushes for the use of the children in the workhouse. The healthiness of the children should more than compensate the guardians for their outlay, which certainly cannot be a very large matter. May many other boards of guardians follow in line. At any rate, the time has gone by when the guardians can regard the supply of tooth-brushes as pampering their charges.

A CASE FOR ASSISTANCE.

A MEDICAL man writes: "I am interested in a boy, aged 15, the son of a solicitor (deceased). There is a large family totally unprovided for. Some of the children are being helped, but this boy is unfortunately an epileptic, and during infancy lost his right arm through an accident. He uses his left hand perfectly. Could you give me the address of a home where it would be possible to have him placed?" Perhaps some of our readers can be of practical assistance in a very hard case, although the medical profession know too well how difficult it is to find places where such cases can be treated.

THE CHEMICAL ANALYSIS OF COAL-TAR DISINFECTANTS.

Mr. T. T. Marchant of University College, London, has pointed out that in the annotation in THE LANCET of May 7th, p. 1283, on the chemical analysis of coal-tar disinfectants, the figure 2 given in the bromine calculation as the last multiplier should be 20. Multiplying by 2 gives the phenols calculated on the bromine figure in 10 grammes of the disinfectant taken for the experiment, but in order to obtain the percentage of phenols the last multiplier should obviously be 20 and not 2.

Lex.—We were confident when we began to read "Lex's" denunciation of the medical profession that it would close with the revelation that the writer was personally suffering from what he believed to be an error on the part of a medical man. We fear that his remedy for what he calls "the utter ignorance of the average so-called qualified practitioner in all the latest developments of medical science" would hardly alter this deplorable state of things, supposing that it existed, for "Lex" thinks that it should be obligatory upon a medical man to take out a yearly certificate, which is only to be granted as a sequel to attendance at lectures! "Lex" should read the Proceedings of the General Medical Council for the last four or five years, for they would disabuse him of his views about medical education.

L. L.—Undoubtedly the winding of the handle is strenuous work for the subject of a weak heart. In some cases such exertion might be dangerous. It is conceivable that the muscular strain might determine a rupture, but it could not cause malignant disease.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B. Dowsett): at 8 P.M.

Discussion:

On Mr. Hopewell Smith's paper on Two Odontoceles and Some Other Cysts (deferred from the April meeting) (opened by Mr. F. J. Bennett and Mr. W. W. James).

Casual Communications:

Mr. Arthur S. Underwood: Some Egyptian Skulls.

Mr. G. Thomson: A Case showing the Result of Extraction of Six-year-old Molars.

Valedictory Remarks by the President.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—A. M. Gossage, A. F. Voelcker): at 5.30 P.M.

Papers:

Dr. George Oliver: A Combination of Tactile and Auscultatory Methods of Reading the Systolic and Diastolic Blood Pressure.

Mr. William Ewart: Dorsal Percussion of the Thorax and of the Stomach, and a New Stomach Sign.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Doree: Clinique (Skin). 5.15 P.M., Lecture:—Dr. T. Hyslop: Disorders of Memory.

TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Dr. R. W. Allen: The Practical Side of Vaccine Treatment.

WEDNESDAY.—4 P.M., Mr. W. Trotter: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. E. C. Hort: The Diagnosis and Treatment of Gastric and Duodenal Ulcer.

THURSDAY.—4 P.M., Dr. J. J. Perkins: Clinique (Medical). 5.15 P.M., Lecture—Mr. A. Edmunds: Intussusception.

FRIDAY.—4 P.M., Dr. E. K. Campbell: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Pritchard: Clinical Pathology.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 11.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Moullin: Gynæcological Cases.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Beddard: Practical Medicine.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. G. Stewart: Chronic Muscular Atrophy of Spinal Origin (with cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld), 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Demonstration:—Dr. G. G. Macdona'd: Vaccine Therapy.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: Gastric Hæmorrhage.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir William Bennett: Stone in Kidney and Ureter.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

MONDAY.—5.15 P.M., Dr. H. Thursfield: Infant Feeding and Food Diseases, illustrated by cases, specimens, skiagrams, and drawings. (Lecture II.). (Post-graduate Course.)
TUESDAY.—5 P.M., Mr. O. L. Addison: General Surgical Diseases, illustrated by cases, specimens, skiagrams, and sketches. (Lecture V.). (Post-graduate Course).
WEDNESDAY.—5.15 P.M., Dr. H. Thursfield: Infant Feeding and Food Diseases, illustrated by cases, specimens, skiagrams, and drawings. (Lecture III.). (Post-Graduate Course.)
THURSDAY.—4 P.M., Lecture:—Mr. Addison: Hernia in Infancy. —5 P.M., Mr. O. L. Addison: General Surgical Diseases, illustrated by cases, specimens, skiagrams, and sketches. (Lecture VI.). (Post-graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Fenton: Arterio-sclerosis with some Remarks upon Treatment.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. J. G. French: Tracheoscopy, &c.
FRIDAY.—3.45 P.M., Lecture;—Mr. C. Nourse: External and Middle Ear.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. H. Tooth.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. T. G. Stewart: Cerebral Abscess.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (29th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (30th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (2nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Anglo-American Pharmaceutical Co., Croydon; Aberdeen University, Secretary of; Mr. T. E. Atkins, South Sylhet; Anglo-Continental Chemical Works, Lond.; Abernethian Society, Lond., Secretaries to the; Dr. H. Aldersmith, West Horsham; Dr. A. E. H. Amer, Achmoun; Mr. W. Alexander, Liverpool; A. H.

B.—Messrs. Blundell and Rigby, Lond.; Mr. T. B Browne, Lond.; Dr. Andrew Balfour, Khartoum; Messrs. Burroughs, Wellcome, and Co., Lond.; Dr. G. Breeze, Tangier; Mr. E. Bougault, Paris; Messrs. J. Bale, Sons, and Danielsson, Lond.; Dr. Mary A. Blair, Lond.; Mr. J. Billmeier, Lond.; Dr. T. B. Broadway, Dorchester; Brussels Exhibition, Office of the Commissioner General, British Section; Mr. F. Acetanilide, harmful effects only in overdoses, 449
Acetonuria, occurrence of, in cases of infectious diseases (Dr. A. Harris), 1346
Acholuria (see Jaundice, acholuric)
Achorn, Dr. J. W., Nature's Help to Happiness (review), 1356
Ackerley, Dr. R., saline waters, and the use and abuse of common salt, 501
Acne vulgaris, treatment by vaccines, 1788; by X rays, 775
Adami, Prof. J.G., Inflammation: Introduction to the Study of Pathology, 1909 (review), 928
Adams *v.* Pomeroy, 246, 395, 671, 754; subscription list, 60, 309; subscriptions for Dr. Martha Adams, 182
Adams, Mr. J. E., acute primary phlegmonous gastritis, notes of a case due to the pneumococcus, 292; thoracoplasty for very large empyema, 240
Adams, Dr. M. (see above: Adams *v.* Pomeroy)
Adams, Mr. P. E. H., discussion on bilateral parotitis and cyclitis, 502
Addison's disease, absence of symptoms of, in extensive yet incomplete fibro-caseous disease of both suprarenal capsules, 368; pathology of, 447
Adenoids, prevalence among London schoolchildren, 594; in infants increased by prone posture in perambulators, 1181
Adenoma, malignant (bile-producing malignant tumour of liver) (Dr. F. Parkes Weber), 1066; of liver, amyloid degeneration in, 925
Adie, J. R., congenital intestinal atresia, 822
Adkins, Mr. G., medical inspection of children in Devonshire, 682
Adnexa, importance of removing uterus in certain diseased conditions of, 862
Adrenal, malignant and non-malignant tumours of bilateral origin, 428
Adrenalin, gauze tape, 1545; hypodermic injection of, in treatment of spasmodic asthma (Dr. B. Melland), 1407; chloride, use of, in treatment of plague (Mr. E. N. Thornton), 994; solution, ampoules of, 1545
Adult, chronic primary intussusception in, 1364
Adulteration, 1513; Acts Relating to (Sir W. J. Bell and Mr. C. F. Lloyd) (review), 1764
Adventitious sounds, occurrence in normal chest, 1086, 1098
Æsthetics of anæsthetics (Dr. F. Hewitt), 623, 821
Affleck, Dr. J. O., discussion on artificially prepared hypnotics, 1694
Africa, British East, Akikúyu of (Prehistoric People) (Mr. W. S. Routledge and Mrs. K. Routledge) (review), 1621; climate and public health in, 1389; German East, plague prevention in, 940; South, health of British Army in (1908), 454
Africa, West, yellow fever in, 1634
After-Care Association, 617
Age Incidence, Sex and Comparative Frequency in Disease, 1909 (Dr. J. G. Andrew) (review), 32
Aggression theory, 1739
Agricultural research, 1502
Aikens, Miss C. A., Clinical Studies for Nurses, 1909 (review), 930; Primary Studies for Nurses, 1909 (review), 180
Air, contaminated by putrid emanations, 1033 (see Hot air)
Air-passages, foreign bodies in (Mr. R. J. Godlee), 1665; tracheotomy for foreign bodies in, 189
Air swallowing, case of, 1537
Akikúyu of British East Africa (Prehistoric People) (Mr. W. S. Routledge and Mrs. K. Routledge) (review), 1621
Albania, defective sanitary service among troops fighting in, 1580
Albuminuria, postural, in boy the subject of (Dr. J. F. Bury and Dr. J. F. Ward), 19
Alcock, Dr. N. H., and Ellison, Dr. F. O'B., Text-book of Experimental Physiology for Students of Medicine, 1909 (review), 1005
Alcohol, administered to baby, 271; brewing of beer containing minimum of, 881; injections of, into superior laryngeal nerve in treatment of dysphagia of laryngeal tuberculosis (Dr. J. Dundas Grant), 1754; sale of, in chemists' shops in United States, 1449; use of, among members of Alpine clubs, 1151; value of, as food, 737
Alcoholic beverages, consumption of, 1111
Alcoholic Drinks, National Expenditure on (Our National Drink Bill, Mr. J. Newton), (review), 34
Alcoholism in Russia, 1044
Alcoholism, insanity due to, 1540; effect of, on offspring, 1784
Aldridge, Mr. G., notes on an interesting case of triplets, 1619
Aldridge, Dr. N. E., simple apparatus for producing rhythmical variations in electrical currents, 104
Ale, India pale, 1007
Aleppo boil, 1233
Alexander, Mr. F. W., "Victim to Science," X ray martyr, 267
Alexander, Prof. G., murderous attack upon, 274
Alexander, Dr. W., freedom of the feeble-minded in the Liverpool workhouse and some of its results, 1783; maternity cases in the Liverpool workhouse hospital during 1907, 1908, and 1909, 1405; note on a case of post-peritoneal hæmatocele complicating a large uterine fibroid, operation, cure, 643, 644
Alexandria, drainage of, 465
Alexandria Hospital for Infectious Diseases in Montreal, 1505
Alimentary canal, external examination of, 361

Alimentation and Nutrition in Normal and Pathological States (Dr. E. Maurel) (review), 1417
Allan, Dr. F. J., discussion on disinfectants, 863
Allan, Dr. G. A., effects of temporary and permanent closure of the cerebral arteries, 926
Allan, Dr. J., enteric fever in infancy, 463; infant mortality and the "soother," 1043; prevalence of tuberculosis among school children, 886
Allan, Dr. J., and Trevelyan, Dr. E. F., painful tonic spasm in the hands, 1141
Allen, Dr. R. W., the bacillus influenzæ and symbiosis, 1263
Allen's Commercial Organic Analysis (review), 1005; vol. ii., 1910 (review), 1696
All-malt beers, 36
Allochiria, diagnostic significance of, 44
Alpine districts, condition of infants in, 336
Alpinism and alcohol, 1151
Alum in toothache (Looking Back), 326
Alyth, outbreak of scarlet fever at, 1378
Amaurosis, puerperal, 1154
Ambulance, metropolitan (Parliamentary question), 1241
Ambulatory treatment of fractures of femur, 273
Amentia and dementia, 980
America, mortality statistics of, 1218
American Proctologic Society, twelfth annual meeting, 1704
American Red Cross, endowment of, 75
Ammon, Dr. v., Sehprobentafeln zur Bestinnung der Sehschärfe für die Ferne, 1909 (review), 1209
Ammonia and sulphates in urine, estimation of, 618
Ammonium chloride inhaler (Varapole brand), 182
Amphibia, pelvic anatomy of, 1394
Ampoules of adrenalin solution, 1545
Ampoules (see Dropper ampoules)
Amputation, interscapulo-thoracic, Mr. Littlewood's method of performing, 1298
Amputations at hip and shoulder (including interscapulo-thoracic) (Mr. C. B. Lockwood), 1185
Amritsar (India), new drainage works at, 613
Amyloid degeneration in an adenoma of liver, 925
Amyot, Dr. J. A., rabies, 1788
Anæmia, pernicious, due to oral sepsis, 1349, 1350; "pernicious," pathology of, 924; pernicious, pigmentation in, 1002; splenic, simulated by chronic malignant endocarditis, 173
Anæsthesia, blood pressure in, 436; general apparatus for administration of oxygenated and warmed ether vapour for, 372; lumbar, present position of, 1442; spinal, death from excess of strychnine employed with, 1288; spinal, enterectomy under, in infant seven months old, recovery (Mr. H. A. T. Fairbank and Dr. W. Vickers), 364; spinal, method of, 1152
Anæsthetic, choice of, 791; general, administration possible, in cases in which pleural fluid is present in thoracic cancer, 979
Anæsthetics, administration of, report of inquiry into question of deaths resulting from, 1087; deaths under (leading article), 1078; legislation in, 886, 1027; æsthetics of, 821, (Dr. F. W. Hewitt), 623; Practical Guide to Administration of, second edition, 1909 (Dr. R. J. Probyn-Williams) (review), 1074
Anæsthetics in "Annus Medicus," 268
Analax, 1210
Analgesia, local and spinal, operation under for prolapsus uteri with severe cardiac disease, 389
Analysis, chemical, of coal-tar disinfectants, 1798; Commercial Organic (Allen's) (review), 1005; vol. ii., 1910 (Allen's) (review), 1696

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—All-malt Beers, 36—Analax, 1210—Brevon Bread, 36—Bread made from Stone-ground flour, 307—Bulgarian Soured-milk Chocolates, 1210—Buvo, 36—Car-ma-me Preparations, 1210—Cyder (Woodbine Blend), 308—Diabetic Raspberry Jam, 653—Galenical Preparations of Calcium Salts, 1007—Geril bread, 308—Glycerine Extract of Red-bone Marrow, 36—Honeycomb mould, 1545—Hooker's milk cocoa, 1545—India Pale Ale, 1007—Infant food, 1545—Isham California Water, 308—Kolynos Dental Cream, 1007—(1) Leucofermanten; and (2) Fibrolysin Guttaplast, 653—Old Sercial Marsala, 653—Oxygenia Water, 36—Pankreon, 653—Phosphated Petroleum Emulsion (Tippee), 36—Porturtle, 653—Poulain's Cocoa, 307—Proteid Foods, 1210—Piutinol, 307—Regulin, 1545—Sanitary slate pencils, 1545—Sauerin liquid culture, 1545—Spade Coffee, 36—"Tabloid" Lodal, 1210—Tabloid Thyroid Gland (standardised), 308—(1) Iodurase; (2) Bromiase; and (3) Lactimase, 307—Thiocol, 653—Trommer's Elixir, 653—(1) Vaccines; (2) Adrenalin gauze tape; (3) Ampoules of adrenalin solution; and (4) Tuberculin (old), 1545—Valerobromine (Lagrand), 653—White Cross Milk, 307—Wormser Winemust, 1210

Anaphylaxis, 1739
Anasarca in pneumonia, 9
Anastomosis, new device for, 1007; of facial and spinal accessory nerve, 611; of nerve, failure of, in infantile palsy (Dr. W. B. Warrington and Mr. R. W. Murray), 912
Anatomy, Quain's Elements of (Prof. E. A. Schafer and Prof. J. Symington) (review), 1364; blastic, proposals to teach anatomy by means of solid pieces capable of being mounted and dismounted (Looking Back), 441; Comparative, of animals (Prof. G. C. Bourne) (review), 306; rôle of, in medical research (leading article), 1486; of heart, recent researches of (Dr. A. Keith and Dr. J. Mackenzie), 101; Human, Gegenbaur's (Prof. M. Fürbringer) (review), 927; medical morbid, and pathology (Dr. H. Thursfield and Dr. W. P. S. Branson) (review), 1209; surgical (Dr. J. A. C. Macewen) (review), 799; surgical, free course of, at Faculty of Medicine, 893; surgical, applied, regionally presented, 1909 (Dr. G. A. Woolsey), 439
Anderson, Lieut.-Col. John Albert, obituary, 1498
Anderson, Dr. J. W., unusual ending in a case of arsenic poisoning, 1138
Andrew, Dr. J. G., Age, Incidence, Sex, and Comparative Frequency in Disease, 1909 (review), 32
Andrewes, Dr. F. W., the Croonian lectures on the behaviour of the leucocytes in infection and immunity, delivered before the Royal College of Physicians of London (Lecture I.), 1737
Andrews, Dr. H. Russell, carcinoma of the cervix of a prolapsed uterus, with contact carcinoma of the vulva, 859; myomectomy during pregnancy, 859
Aneurysm, arterio-venous, case of, 1538; occurrence of, in various parts of body, 1520; William Hunter's account of, 1518
Aneurysm of descending thoracic aorta associated with dilatation of arch, 571; innominate, 1352
Angina, cerebral features of, 702; extra-pectoral forms, 700; peripheral, 700; respiratory features of, 701
Angina abdominis, 700
Angina pectoris (Prof. W. Osler), 697, 839, 973; attack and simple gastro-circulatory seizure, comparison made between (Mr. W. Verdon), 1679; prognosis, 973; in relation to etiology, 973; individual history, character of attacks, and vascular condition, 974; clinical types, 698; etiology, 697; forms of, 975; treatment, 976; nature and treatment of (Dr. A. Morison), 98
Angioma, large, cure by radium, 1563; spreading, case of, 435
Animal Physiology, Elements of (Prof. W. A. Osborne) (review), 1005
Animal tissues and radio-activity, 173
Animals, Atrophic Form of Rabies occurring in (Maj. G. Lamb and Capt. A. G. McKendrick) (review), 865; Comparative Anatomy of (Prof. G. C. Bourne) (review), 306; living, experiments on, 1729; (Parliamentary question), 1041; lower than man, streptotrichæ parasitic and pathogenic for, 555; mythical wild (myth and science), 808; (Notification of Disease) Order of 1910 (leading article), 732; outbreaks of anthrax amongst (Parliamentary question), 967
Ankylosis of both hips in association with coxa valga, 1413
Ankylostomiasis, menace to industrial life of non-tropical countries (Sir T. Oliver), 356
Ankylostomum duodenale, 1412
Annals of Ophthalmology (review), 651
Annals of Tropical Medicine and Parasitology (review), 30
Anning, Mr. G. P., congenital thoracic deformity, 1141
Annus Medicus, anæsthetics in, 268
Annus Medicus (1909), correction of oversight in, 69
Anæmia, pernicious, metastases in bone marrow and blood suggestive of, in latent cancer of stomach, 1562
Anæmia, secondary, origin and treatment, 1720
Anæsthesia, spinal, in children and infants, (Mr. H. T. Gray), 1611
Anæsthesia (see Chloroform anæsthesia)
Antarctic expedition, Capt. Scott's, 120
Anthrax, death from, 824; deaths from, in Liverpool, 608, 957; deaths from (Parliamentary question), 899; Order revised, 1729; outbreaks of, amongst animals (Parliamentary question), 967; prevalence of, 682; spread of, decision of Furness and District Farmers' Association concerning, 824
Anthropology, criminal, congress on, 1234
Human Species considered from Standpoints of Comparative Anatomy, Physiology, Pathology, and Bacteriology (Prof. L. Hopf) (review), 1073
Antimony compounds in treatment of trypanosomiasis, 938
Antipyrin, harmful effects, only in overdoses, 449
Antisepsis and asepsis in midwifery practice (leading article), 1148
Antisepsis and sepsis, 128, 202, 267, 329
Antitetanus serum, supply in London, 1098
Antithyroid and thyroid preparations, action of, 367
Antituberculosis campaign, 1723; summary of, 1173; in Ireland, 1650; in London (Dr. D. J. Williamson), 876
Antituberculosis Exhibition, 217
Antivivisection Hospital, deaths from neglect at, 79
Antivivisectionist campaign, 895
Antrim, county, Infirmary, 1232
Antrum, left maxillary, rapidly growing soft fibroma removed from posterior wall of, by Rouge's operation, 792
Aorta, abdominal embolism of, with mitral stenosis and thrombosis of pulmonary veins, death (Dr. S. P. Phillips), 1065; death from perforation of, by halfpenny impacted in œsophagus (Mr. G. G. Turner), 1335; descending thoracic, aneurysm of, associated with dilatation of arch, 571
Aortic insufficiency after rupture of valve, 612
Apocynum cannabinum, pharmacology of, 81
Apoplexy, traumatic late, or late traumatic subdural hæmorrhage, 463
Apothecaries' Hall of Ireland, negotiations with General Medical Council, 1102; pass lists, 1386; report on Final Examination submitted to General Medical Council, 1553
Apparatus, clinical, for obtaining graphic records of blood pressure (Dr. C. Singer), 365
Appendicectomy, gastric analyses after, in cases of appendicular gastralgia, 710
Appendicitis, 1001; acute, two cases of pelvic tumour associated with, 1353; complicating pregnancy at seven months, 647; discussion on, 1442; general peritonitis and obstruction, patient exhibited after operation for, 28; priapism complicating, 470; question of contagion of, 1645; suppurative and perforated gastric ulcer, simultaneous occurrence (Mr. C. A. Moore), 103, 119
Appendicitis in German Navy, 886
Appendicostomy, indications for, 188
Appendix, cancer of, 1442; disease of, as cause of gastric symptoms (Mr. H. J. Paterson), 708; disease of, as cause of, gastric symptoms, evidence, 710; latent disease of, connexion of gastric hypersecretion with (Dr. W. S. Fenwick), 706; vermiform, effects of irritation confined to mucous membrane of, 1538
Appendix cæci, streptothricial infection of, 630
Appendix vermiform, malignant disease of, treatment with emanations of radium (Sir T. Lauder Brunton and Dr. L. G. Glover), 419
Appliances, modern diagnostic, demonstrations of, 1176
Appointments, medical and surgical, of H.M. King George V., 1704
Appointments, weekly lists of, 80, 141, 216, 279, 341, 409, 471, 545, 617, 691, 764, 833, 900, 968, 1041, 1110, 1179, 1241, 1315, 1388, 1450, 1511, 1592, 1660, 1731, 1795
Apponyi, Count, conferment of medical degree upon, 174
April at home and abroad, 1365
Apuleius of Madaura, Apologia and Florida of, translated by H. E. Butler, 1909 (review), 31
Archives of Internal Medicine (review), 652, 1075
Arctic regions, irritability of temper developed by prolonged stay in, 1283
Arm, dropsical, of breast cancer, pathology of, 977; dropsical, only manifestations of active malignant disease, 978; dry gangrene of, 1349; right, complete hysterical paralysis of, in child, 1272
Arm and face (right) paralysed, 1413
Armagh Asylum, additional accommodation needed, 72
Armour, Mr. D. J., treatment of brain tumours, 863
Armour, Dr. E. F., discussion on rational puerperium, 372
Armstrong, Dr. H., notes of a case of heart-block occurring in a boy aged 5½ years, 105
Armstrong, Prof. H. E., position and method of science teaching in secondary schools, 250, 329

Armstrong, Mr. W., discussion on arthritis deformans, 1201
Army, British, cigarette smoking in, 384; diseases in, official parliamentary statement as to, 833; health of (1908), 322, 453; health in India (1908), 454, 1567; health of, in Mediteraneanarea (1908), 453; health of, in South Africa (1908), 454; state of (leading article), 934; invaliding in, for tuberculosis (Parliamentary question), 763
Army dentists in India, 1582
Army Estimates, as affecting medical branch of service, 761
Army Medical Officers' Widows Fund, 1572
Army medical services, inspector of (Parliamentary question), 761
Army medical unrest, 936
Army, native, of India, health of, 1639
Arnsperger, Dr. H., Die Röntgenuntersuchung der Brustorgane und ihre Ergebnisse für Physiologie und Pathologie, 1909 (review), 180
Arris and Gale lectures on some embryological problems in relation to medicine (Prof. P. Thompson), 1247, 1321
Arris and Gale lectures on some problems relating to the evolution of the brain (Prof G. E. Smith), 1, 147, 221; on the physiology of the human labyrinth (Mr. S. Scott), 1601
Arsenic poisoning, unusual ending in case of, 1138
Art Production (Burlington Magazine) (review), 1075
Art and science in medicine, 1115
Arterial, hypertension, fatty degeneration of, 1536
Arteries, cerebral, effects of temporary and permanent closure of, 926; of Gastro-intestinal Tract with Inoculation Circle (Dr. B. Robinson) (review), 108; microscopic structure of, 50; and veins, naked-eye difference between, 50
Artery, punctured wound of, through vein, results of, 1519
Artery, spermatic, ligature of, in operation for varicocele, 588
Arthritic diathesis, 1084; in relation to gout, 1084
Arthritis, acute, of doubtful origin, 1154; acute, of doubtful origin (Dr. G. B. Buchanan), 1124; deformans, 859; deformans (Dr. R. L. Jones), 997; dry, treatment by injection of vaseline, 1086; gonorrhœal, four cases treated by vaccine therapy, 575; infective, 1142; sporotrichosic, of knee, 273; tuberculous, undescribed bone changes in hand associated with, 1273
Artisans' dwellings in Dublin, importance of open spaces around, 72
Arylarsonate, injection of, in treatment of phthisis and other conditions, 176
Arylarsonate and mercury combined, in treatment of syphilis (Col. F. J. Lambkin), 23
Arylarsonates, optic atrophy following use of, in syphilis, 1690
Ascites, operative treatment of, 1053; by femoral drainage, 1053
Asepsis and antisepsis, 128, 202, 267, 329; in midwifery practice (leading article), 1148
Ashforth, Mr. T. L., duties of a public vaccinator, 1514
Asphyxia, medico-legal aspects of death from, 797; traumatic, and injury to tracheal plexus, 646
Aspiration, technique of, in treatment of tuberculous abscesses of bony origin (Dr. J. Calvé and Dr. H. J. Gauvain), 635
Assam, Pasteur Institute for, 1235; vaccination in, 76
Assassination, pathological, 1630
Assistant-surgeons, military (Parliamentary question), 761
Association, independent activity of lower centres of, 1051; lower cerebral, defective control of processes of, in mental disease, 1050
Association of Certificated Dispensers, annual meeting, 831
Association of Fellows of the Royal College of Surgeons in Ireland, 1387
Association of Medical Diplomates of Scotland, 1499
Association of Medical Officers of Health, 966, 1314, 1590, 1644
Asthma, bronchial, expiratory nature of stridor in, 1499; spasmodic, treatment of, by hypodermic injection of adrenalin (Dr. B. Melland), 1407; treatment of, 1350
Astragalus, fracture of neck of, in case of old-standing forward dislocation of foot, 1071
Astronomy, Chats on (Mr. H. P. Hollis) (review), 1697
Asylum accommodation in Russia for insane persons, 516
Asylum attendants in Ireland (Parliamentary question), 1241
Asylum officers' superannuation (Parliamentary question), 1178
Asylum Workers' Association, 1591
Asylums, county, deaths in (Parliamentary question), 1041
Ataxia, Friedreich's (Dr. A. R. Moody), 164
Ataxic type of general paralysis, case of, 1539
Ateleosis, case of, 1537
Athletics in France and Italy, 1630; at University of Bristol, 1647
Athletics, use and possible abuse of, during period of growth and development, 794
Atkinson, Dr. J. M., the climate of Hong-Kong, with account of journey from there to London, 1097
Atkinson, Dr. S. B., death of, 256; obituary, 339
Atlantic, North, Scientific and Biological Researches in, 1909 (Dr. R. N. Wolfenden) (review), 727
Atmosphere (see Electricity, atmospheric); and medicine, 1705
Atmospheres, noxious, life-saving apparatus for use in, prize of Royal Society of Arts for, 143
Atresia, congenital intestinal, 822
Atropine in treatment of tetanus, 1430
Attendance, medical, question of responsibility, 1493
Aubertin, M., death after recovery from chloroform anæsthesia, 73
"Audio," a disclaimer, 533

Resignation of Dr. Charles Sheard, medical officer of health of Toronto; Bill for the Sterilisation of Criminals, Idiots, and Imbeciles; Amendments in the regulations of the Ontario Medical Council; Farm inspection of milk supplied to Montreal; Children poisoned by pills in Canada, 1506

Canada, exophthalmic goitre not prevalent in, 1787; medical education in, 1788
Canadian Medical Association, annual meeting, 1787; official journal for, 278
Cancer, abdominal, conditions simulating 73; of appendix, 1442; of breast, dropsical arm of, pathology, 977; with bone metastases, condition of blood, 1684; of endometrium in specimen of myomatous uterus, 28; of large intestine, 574; mouse, experimental diminution of resistance to (Dr. A. Leitch), 991; (leading article), 1011; of ovary, proportion of, to innocent growths, 370; of penis, 614; of pylorus, radical operation for, 498; of stomach, classification of cases, 415; diagnosis by chemical and other methods, 417; diagnosis, value of gastroscope in, 418; early diagnosis of, 533, 752, 822, 888; early diagnosis (Mr. C. M. Moullin), 415; early diagnosis, successful operation dependent on, 415; early symptoms, 416; relation to ulcer, 415; radium in surgical treatment of, 1791; uterine, radium in treatment of, 136
Cancer, early, of common bile-duct, 1349; early treatment, 1646; implantation of, contrast in reactions to, after inoculation of living and mechanically disintegrated cells (Dr. M. Haaland), 787; inoperable, treatment of, 1442; inoperable, of tongue, treatment, 1140; International Conference for the Study of, date of meeting, 1443; isohæmolysis in, 795; latent, of œsophagus, 30; latent, of stomach, with metastases in bone marrow and blood, suggestive of pernicious anæmia, 1562; mode of origin in various regions of body, 752, 753; nature of (leading article), 1557; possible connexion of onset with effects of uncontrolled irradiation, 448; prophylaxis, general principles (Dr. A. T. Brand), 1471; recurrence of, 18 years after amputation of breast, 520; Registrar-General's annual report on, for 1908, 262; solid œdema due to, 977; specificity of (Dr. A. T. Brand), 1471; surgical treatment of, as branch of lymphatic surgery, 1055; treatment, general principles (Dr. A. T. Brand), 1471; treatment by vaccine prepared from cancer growth, 1228; treatment by X rays, 775
Cancer research in United States, munificent aid towards, 1445
Cancer research, recent (leading article), 1001
Cane, Mr. F. E., obituary, 1726
Cannizzaro, Prof. S., obituary, 1368
Cape of Good Hope, Colony of, report on public health in 1908, 669
Capillaries, resistance of, to progressive yielding under influence of, 591
Cappe, Mr. H. N., obituary, 1447
Carbon dioxide snow in treatment of xeroderma pigmentosum, 1350; solid, in treatment of nævus, 798; use of (Dr. E. R. Morton), 1268
Carbon monoxide poisoning followed by insanity, 1352
Carbonic anhydride snow (see Snow)
Carbuncle, arrest of, 1785
Carcinoma, extrinsic, of larynx, 241; recurrent, affecting cerebro-spinal system, 302; relation of, to chronic mastitis (Mr. C. B. Lockwood), 285, 316
Carcinoma of cervix of prolapsed uterus with contact carcinoma of vulva, 859; of pelvic colon, removal of, 300; of pharynx, unusual cases, 540; supervening on tuberculous lesions, 316
Carcinoma (see Lupus carcinoma); occurring in mice, effects of serum upon (Dr. C. Walker), 990; (leading article), 1011
Cardale, Dr. H. J., accident claims as affecting the medical profession, 1027
Cardiac lesion, permanent, in case of acute visceral syphilis, 646
Cardiff, "consultation for infants" in, 824; extension of, 958; health of, 467; tuberculosis dispensary for, 1503
Cardiff City Mental Hospital, recommendation for appointment of physiological chemist, 71
Cardiff Infirmary, 271, 609
Cardiff Medical School, 609
Cardiff Port Sanitary Authority, 1170
Cardiolysis, case of, 1690
Carless, Mr. A., Dupuytren's contraction treated by fibrolysin, 240
Carling, Mr. E. Rock, and King, Mr. L. R., case of "typhoid spine," 1136
Carlyll, Dr. H. B., sarcomatous tumour, 1538
Carmichael, Mr. E. W. S., some indications for vaginal fixation in uterine displacement, 576
Carnegie Trust, 134
Carnell, Mr. E., control of scarlet fever and hospitals for infectious diseases, 953
Carnivora, pelvic floor muscles in, 1459
Carpenter, Dr. George, the late, 1072; obituary, 1036
Carr, Dr. J. Walter, case of (?) myosites fibrosa, 1537; specimen of urinary organs after death with symptoms of uræmia, 721
Carriage, Dr. Richard's horseless, 56, 57
Carrier cases of enteric fever, annual report of medical officer of Local Government Board concerning, 1021
Carrier, infantile, of enteric fever infection, 301; paratyphoid, 661
Carriers, chronic, transmission of typhoid fever by, 516; chronic, of typhoid fever, transmission by (leading article), 113; meningococcus, treatment of, 1217
Carruthers, Dr. D. A., discussion on medical treatment of school children, 574
Carshalton Children's Infirmary (Parliamentary question), 1040
Carteighe, late Mr. M., 1565
Cartilage, fœtal, grafting of, report on, 570
Cartilages, semilunar displacements of (Dr. K. H. Digby), 165
Carwardine, Mr. T., ruptured tubal pregnancy, 859; 12 successive cases of perforation of the stomach or duodenum with 11 recoveries, 239
Casper, Prof. L., Text-book of Genito-urinary Diseases, 1909 (review), 376; two unusual cases of chronic retention of urine, 940
Cassidy, Dr. L. L., specimen of superfœtation taken from a cat, 1477
Castellani, Dr. A., and Chalmers, Dr. A. J., Manual of Tropical Medicine, 1910 (review), 1622
Cat, specimen of superfœtation from, 1477
Cataract, congenital, inheritance in nine families, 1690; extraction of, in capsule, 955
Catarrh, dry, of ear, fibrolysin in treatment of, 240
Cathcart, Mr. C. W., discussion on athletics and physical development, 795; effects of irritation confined to the mucous membrane of the vermiform appendix, 1538
Cathcart, Mr. C. W., and Caird, Mr. F. M., Surgical Handbook for the Use of Students, Practitioners, House Surgeons, and Dressers, 1910 (review), 1543
Cathcart, Dr. G. C., case of enormous tumefaction of epiglottis, exhibited, 1071
Cattle, Dr. C. H., milk, sweet and sour, 30
Caussade, M., and Queste, M., treatment of sciatic neuralgia, 272
Caudo-pelvic muscles, homology of, 1462, 1463
Caviare, suggested communication of leprosy by means of, 1043
Caxton Convalescent Home, Limpsfield, Surrey, annual meeting, 731
Cell-lamination of pre-central gyrus, 1047
Cell proliferation, 863
Cells, living and mechanically disintegrated: contrast in reactions to implantation of cancer after inoculation of (Dr. M. Haaland), 787
Cells and fluids of body, action of, in prevention and cure of disease, 647
Cells of malignant tumours retaining some metabolic or other functional characteristics of cell-type from which they are derived (Dr. F. Parkes Weber), 1066
Census, 1729; census and the birth-rate (Parliamentary question), 1795; of spectacles, 1797
Centenarian, medical (Mr. Edgar Jones), 216
Centenarians, 899, 1039, 1176; cases of, 760, 789; death of, 1268; instances of, 78; Mrs. Margaret Arthurs, 331 (see also Super-centenarian)
Centenary of Bristol Eye Hospital, 1783; of Hufeland Medical Society, 469
Central Midwives Board, 60, 408, 898, 1222, 1589; meeting of, 731, 1313; representation of midwives on, 1716, 1784
Central Provinces of India, hospitals and dispensaries of, 1434; lunatic asylums, 1436
Centralblatt für Allgemeine Pathologie und Pathologische Anatomie (review), 652
Cerebellum, 433; abscess of, differential diagnosis from acute suppurative labyrinthitis (Dr. J. Harper), 1266; disease of, case exhibited, 798; diseases of, 433, 722
Cerebellum and its affections, 571
Cerebral features of angina, 702
Cerebral hemisphere, hemiatrophy of, 432
Cerebro-spinal fever (see Meningitis, cerebro-spinal epidemic)
Cerebro-spinal fluid, examination of, 1621
Certificate, medical referee's form of, in case of workman's compensation, 581; (see also Death certificate)
Certificates, medical, question of, 1299; of cause of death and future legislation, 1092
Cervix, squamous epithelioma of vaginal portion, specimen of uterus and appendages removed by abdominal hysterectomy for, 1141; of prolapsed uterus, carcinoma of, with contact carcinoma of vulva, 859
Cesspools, percolation, 1791
Ceylon, death of Aberdeen medical man in, 1379
Chagas, Dr. C., new form of human trypanosomiasis, 1774
Chalmers, Dr. A. J., and Castellani, Dr. A., Manual of Tropical Medicine, 1910 (review), 1622
Chamberlain, Maj. W. P., statistical studies of the uncinariasis among white men in the Philippines, 1228

Fibroid, necrotic submucous, of uterus, 647; submucous cervical and papillary sarcoma of corpus, uterus containing, exhibited, 797; submucous, partly sarcomatous, uterus containing, exhibited, 797; uterine, with red degeneration, 301, 302; in pregnant uterus, 1142
Fibroid tumour, necrosed and suppurating, treatment by abdominal hysterectomy 63 hours after labour, 26; uterus removed by abdominal hysterectomy for, 1413; of uterus, case of post-peritoneal hæmatocele complicating, operation, cure, 643; traumatic rupture of, with intraperitoneal hæmorrhage, 647
Fibroids, red degeneration of, 1142; treated by electricity, 349
Fibrolipen guttaplast, 653
Fibrolipoma of pharynx, 372
Fibrolysin, injections of, in treatment of stricture of rectum, 240; in treatment of dry catarrh of the ear, 240; in treatment of Dupuytren's contraction, 240; in treatment of sciatica, 240
Fibroma, large, of ovarian ligament and contiguous portion of ovary, 1142; soft, rapidly growing, from posterior wall of left maxillary antrum removed by Rouge's operation, 792
Fibromyomata, uterine, practical points in life-history of, 1693; of uterus, life-history of, contribution to, 1689
Fibrosis of lungs, varieties of, 1521; relation of pneumonia to, 10; relation of, to tuberculosis (Dr. C. T. Williams), 1521
Fibrosis uteri, specimen of, removed by vaginal hysterectomy, 1141
Fibrositis, etiology, 713; pathology, 713; treatment, 714; various forms of, 713
Fibula, displacement on tibia in case of old-standing forward dislocation of foot, 1071; fracture of, and epiphyseal detachment of lower end of tibia, 336
Fiction, medicine in, 1441; (leading article), 1282
Fiddian, Dr. A. P. (obituary), 1591
"Figaro (Le)," poetical comment in, on annotation in THE LANCET as to moustaches, 81
Filtre (Shipwright pressure), 548
Finance Act and medical men, 1314
Findlay, Dr. L., natural and unnatural feeding of the infant, 119
Findley, Dr. P., Gonorrhœa in Women, 1909 (review), 1073
Fine Art Society, pictures illustrating disposal of dead by burning in India, 473
Finger-print identification, 940
Finlay, Dr. Carlos J., work of, in respect of insect-borne disease, 1715
Finny, Dr. J. M., discolouration of the skin, 1002; discussion on glycosuria and Graves's disease, 301; discussion on treatment of gastric ulcer, 301
Finzi, Dr. N. S, case of sarcoma of the ear and mastoid region under radium treatment, 1070
Finzi, Dr. N. S., and Hill, Dr. W., case of malignant growth in the neck treated with radium, with recurrence in the mediastinum, 1070; case of œsophageal growth under treatment by radium, 1070
Fire at Haslar Hospital, 952; at a Liverpool hospital, 617
Fire-extinguishing exhibition, 471
Fireguards and flannelette, 957
First aid, abuse of, 1317
First aid in strychnine poisoning, 902
Firth, Mr. A. C. D., and Rolleston, Dr. H. D., case of hemiatrophy of the cerebral hemisphere, 432
Fischer, Dr. G., Bau und Entwickelung der Mundhöhle des Menschen unter Berücksichtigung der vergleichenden Anatomie des Gebisses und mit Einschluss der speziellen mikroskopischen Technik, Lehrbuch für Zahnärzte, Aerzte, und Studierende (The Structure and Development of the Human Mouth), 1909 (review), 109
Fish, Dr. C. E., civilisation and the corset, 397
Fish, destruction of mosquitoes' larvæ by, in Soudan (Dr. A. Balfour), 100
Fisher, Mr. J. H., congenital word-blindness, 1348
Fishes, pelvic anatomy of, 1393
Fisiologia General (Dr. L. R. Lavin and Dr. A. P. Sumer (review), 1622
Fistula, biliary, case shown after operation for removal of, 435; labyrinthine and spontaneous nystagmus in case of chronic suppurative otitis media (Mr. L. Sewell), 25; tuberculous, treatment by injections of subnitrate of bismuth, 335; uretero-vesico-vaginal, use of finest silk in preference to catgut in cases of, 301
Fitzwilliams, Mr. D. C. L., case of congenital dislocation of the left knee, 1139; case of traumatic dislocation of the knee, 1139
Flames, presence of ozone in, 192
Flannelette and fireguards, 957
Flap incision, small, for glaucoma, 1348
Flea, musical, 1363
Fleming, Mr. A., discussion on syphilis, 1758
Flemming, Mr. C. E. S., State registration of nurses, 461
Fletcher, Mr. H. N., ectopic gestation, 504; exhibition of a pregnant tube, 1414
Fletcher, Dr. J., enteric fever in infancy, 754; presentation to, 1647
Fletcher, Dr. R., career of, 1219
Flexner and Jobling's serum (see Serum, Flexner and Jobling's)
Flies, effect of, on spread of typhoid fever in India, 827 (see Tsetse flies)
Floods in Paris, 335, 390, 403, 464, 538; conditions after, 685; effect of, on public health, 960, 1028; maintenance of public health by means of disinfection during and after, 754, 889; and public health, 534, 604; a reassurance, 676
Florida and Apologia of Apuleius of Madaura, 1909 (translated by H. E. Butler) (review), 31
Flour, bleached, simple test for, 1489; stone-ground, bread made from, 307
Fluids and cells of body, action of, in prevention and cure of disease, 647
Flux, Mr. A. W., urban vital statistics in England and Germany, 587
Food adulteration in England and France, 371; adulteration in United States (Parliamentary question), 1240; estimation of value of alcohol as, 737; purity of, 1513; (see Infant food); Inspection and Analysis (Mr. A. E. Leach) (review), 1418; poisoning, 1724
Foods, cold storage of, legislative control of, in United States, 1173; oxalic acid in, 1016; proteid, 1210
Foot, old-standing forward dislocation, with fracture of neck of astragalus, and displacement of fibula on tibia, case shown after operation, 1071; and leg, lymphatic œdema of, with cyanosis and drop-foot (Sir H. Morris), 1455
Football, injuries from, in United States, 43; (see Inter-hospital Rugby cup-ties)
Forbes-Ross, Dr. F. W., new anastomosis device, 1008
Forceps, fine long, 654
Fordyce, Dr. A. D., exhibition of infants treated by staphylococcic vaccine for multiple boils or abscesses, 27; prevalence of tuberculosis among school children, 820
Foreign bodies, beneficient (leading article), 582; in air-passages (Mr. R. J. Godlee), 1665; tracheotomy for, 189; in bronchi (leading article), 1280
Foreign body, removal from left eye, 1350; in interior of eye, two cases, 1206; in lung, 500; in œsophagus, 500
Foreign countries, lessons from, respecting organisation of medical profession (leading article), 38
Foreign medical men, conditions of admission to practise in Turkey, 74; deaths of, 139, 276, 340, 408, 471, 542, 615, 759, 1037, 1105, 1174, 1448, 1507, 1589, 1727
Forfar Infirmary improvements, 610
Formaldehyde process of meat preservation (Parliamentary question), 833
Forres Leanchoil Hospital, annual meeting, 468
Forsyth, Dr. D., case of congenital œdema with dilatation of the intestinal lymphatics, 432; case of non-cretinous mental deficiency, with goitre, 722; extract of parathyroid gland, 202
Forsyth, Dr. J. A. C., discussion on acute hæmorrhagic pancreatitis, 1620
Foster, Sir W., retirement of, 617
Fothergill, Dr. W. E., chronic results of septic and gonorrhœal infection of the female pelvic organs, opening of discussion upon, 106, 1142; hypertrophied uterus, 301; large fibroma of the ovarian ligament and contiguous portion of the ovary, 1142; ruptured cornual pregnancy, 301
Foulerton, Mr. A. G. R., streptotrichoses and tuberculosis (Milroy lectures delivered before the Royal College of Physicians of London), 551, 626, 769; (leading article), 802
Fourmestraux, M. de, treatment of tuberculous fistulæ by injections of subnitrate of bismuth, 335
Fowl (see Wild fowl)
Fowler, Dr. J. S., and Dickson, Dr. W. E. C., tuberose sclerosis, 1351
Fox, Dr. L. W., Practical Treatise on Ophthalmology, 1910 (review), 1004

Medical relief, gratuitous, in Scotland, 595
Medical research, Beit Memorial Fellowship for, 670, 681; disposal of funds for, 269; lay view of, 252; rôle of comparative anatomy in (leading article, 1486
Medical schools, grants to (Parliamentary question), 1239
Medical schools of France, students' guide to, 46
Medical service, free proposal for, 664
Medical Sickness and Accident Society, 79, 365, 689, 1189

MEDICAL SOCIETIES.

ÆSCULAPIAN SOCIETY.—Pituitary extract, 724—Present position of Cæsarean section in obstetrics, 436—Study of case of mitral construction, 303—Use of vaccines in acute streptococcal infections, 241

BERLIN MEDICAL SOCIETY.—Demonstration of cases, 758

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—Acute appendicitis; hypnotics; exhibition of cases and specimens, 927—Brain abscess, 303—Exhibition of cases, 1273—Oral sepsis, 1414—Some remarks on the treatment of fractures, 647

BRADFORD MEDICO-CHIRURGICAL SOCIETY AND BRADFORD DIVISION OF THE BRITISH MEDICAL ASSOCIATION.—Exhibition of cases, 30

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases, 1414—Exhibition of cases; Ectopic gestation, 504—Exhibition of cases and specimens; Early operation in appendicitis; Strangulation of the epididymis and testis by torsion, 175—Some points of interest revealed by the medical inspection of 2000 school children; Exhibition of specimens, 797—Some observations on infective arthritis, 1142

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—Some cases of bacillus coli infection of the urinary tract; Jejunal ulceration not post-operative; Malignant and non-malignant tumours of bilateral origin, 302

CHELSEA CLINICAL SOCIETY.—Method of direct examination of the larynx, trachea, bronchi, and œsophagus with Brünings' instruments, 576

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Athletics and physical development, 794—Demonstrations; Exhibition of patients; Gonorrhœal urethritis; Tuberose sclerosis; Ménière's disease and facial paralysis, 1350—Discussion on syphilis and marriage; Treatment of phthisis and other conditions by injection of arylarsonates; Cremation, 175—

Exhibition of cases, 27—Exhibition of cases; Rich protein diet in relation to gout and the thyroid gland; Blood pressure in anæsthesia; Prostatism, 435, 436—Suprapubic transverse fascial incision; Bacillus coli infection of urinary tracts in pregnancy, 1476—Exhibition of cases, 1538—Artificially prepared hypnotics; Lupus carcinoma; Cammidge reaction, 1690

EDINBURGH OBSTETRICAL SOCIETY. — Adjourned discussion on the rational puerperium; Ovarian epilepsy, 372—Importance of removing the uterus in certain diseased conditions of the adnexa; Uterus bicornis; Antenatal lobar pneumonia, 862—Rational puerperium 29—Some indications for vaginal fixation in uterine displacement; Simple perineal operation for relaxed vaginal outlet, 576—Treatment of vomiting following chloroform anæsthesia; Practical points in the life-history of uterine fibromyomata; Pelvic abscess, 1692, 1693

HARVEIAN SOCIETY OF LONDON.—Exhibition of cases, 374—Exhibition of cases and specimens, 1352—Surgeons, some mortals, and the climacteric; Treatment of indigestion, 1205—Some points in middle-ear suppuration, its sequelæ and treatment, 575—Treatment of labour in contracted pelves, 793

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Action of radium on tissues; Ferric chloride reaction in diabetes; Exhibition of specimens, 1002; Congenital talipes; Difficulties in prescribing and wearing glasses; Exhibition of cases and specimens, 1412—Diagnosis in states of depression; Exhibition of cases, 1141—Exhibition of cases, 106—Gonorrhœa and gonorrhœal infection; Exhibition of specimens, 572—Isohæmolysis; Wertheim's hysterectomy; Exhibition of cases and specimens, 795—Treatment of hæmorrhoids; Use of the cystoscope; Abdominal effusions; Apparatus for anæsthesia; Exhibition of cases and specimens, 371

LIFE ASSURANCE MEDICAL OFFICERS' ASSOCIATION.—Presidential address on the medical examiner in life assurance, 702

LIVERPOOL MEDICAL INSTITUTION.—Cardiac syphilis; Chronic prostatitis; Fat compounds, 646—Cerebro-spinal rhinorrhœa; Appendicitis; Traumatic neuroses, 1001—Demonstrations of specimens; Solid carbon-dioxide; Heart-block, 105—Duodenal ulcer, 436—Exhibition of cases; Acid-fast bacilli in tuberculous stools; Spirochæta pallida, 1140, 1141—Exhibition of cases; Multiple myelomata; Senile heart, 1272—Exhibition of specimens, 30—Exhibition of specimens; Pathology of prostatic enlargement, 796, 797—Exhibition of specimens; Syphilis of the heart; Prostration following sea-sickness; Description of cases, 503—Ureteral calculi and X ray diagnosis; Value of serum- and vaccine-therapy, 861

MANCHESTER MEDICAL SOCIETY.—Surgery of faucial tonsils; Serum diagnosis of syphilis; Chronic cruro-genital eczema, 1072

MEDICAL SOCIETY OF LONDON.—Ankylostomum duodenale, 1412—Atypical pneumonia, 645—Cerebellum and its affections, 433, 722—Colitis, 792—Exhibition of cases, 300, 571, 1071—Exhibition of pathological specimens, 173—Gastroptosis, 1203—Hæmorrhage from an unenlarged uterus; Removal of part of bladder wall, 591—Annual oration and conversazione, 1475

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—Exhibition of cases, 107, 1206—Exhibition of cases and specimens, 798—Examination of fæces in medical practice; Cystoscopic cases; Effects of closure of cerebral arteries, 926—Injections of bacterial vaccines; Gonorrhœal arthritis treated by vaccine-therapy, 575—Significance of certain changes in the composition of the urine, 503

MEDICO-LEGAL SOCIETY.—Death penalty, 796—Deodands; Malpraxis in ancient law, 1030—Food adulteration in England and France, 371—Legal responsibilities of hospital authorities, 1273

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—Electric-bath treatment and excretion of creatinine; Typhoid carrier infection, 793—Treatment of general paralysis by means of serum; Insanity following carbon monoxide poisoning; Treatment of mental disorder, 1352—Insanity as disorder of conduct; Examination of cerebro-spinal fluid; Toxic and exhaustion psychoses, 1620

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Conduct of gynæcological cœliotomy, 105—Exhibition of cases, 301—Exhibition of cases; Cæsarean section; Red degeneration of fibroids, 1142—Intraperitoneal hæmorrhage; Cases and specimens, 925—Ovarian tumours; Exhibition and reports of cases, 647—Vaginal subtotal hysterectomy; Some points in the prognosis of eclampsia; Reports of cases and exhibition of specimens, 1353

NORTHERN ASSOCIATION OF MEDICAL WOMEN.—Medical inspection of school children, 724

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—Exhibition of cases, 373

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Bacterial disturbance of digestion and the consequences, 503—Diabetes insipidus; Intestinal obstruction, 1142 — Discussion on treatment of gastric and duodenal ulcers; Exhibition of cases and specimens, 927—Exhibition of cases, 793—Exhibition of cases; Craniotomy, 1205—Killian's submucous resection of the nasal septum, 374—Milk: sweet and sour, 30—Surgical odds and ends; Exhibition of specimens, 177

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY in conjunction with NOTTINGHAM DIVISION OF THE BRITISH MEDICAL ASSOCIATION.—Discussion on activity of the cells and fluids of the body in the prevention and cure of disease, 647

OPHTHALMOLOGICAL SOCIETY.—Bilateral ophthalmoplegia in an infant; Anterior synechiæ with buphthalmos, 434—Exhibition of cases, 501—Small flap incision for glaucoma; Congenital word-blindness; Hypopyon keratitis treated by pyocyanase; Exhibition of cases, 1348—Xerosis conjunctivæ and nyctalopia; Panophthalmitis; Exhibition of cases, 830 — Optic atrophy, following use of arylarsonates in syphilis Congenital cataract; Exhibition of cases, 1690

OXFORD MEDICAL SOCIETY.—Demonstration of the gastroscope, 863—Exhibition of cases; Alcoholic insanity, 1539, 1540

PATHOLOGICAL SOCIETY OF MANCHESTER.—Cell proliferation; Pathology and treatment of otitic meningitis, 863—Chronic results of septic and gonorrhœal infection of the female pelvic organs, 1142

RÖNTGEN SOCIETY.—Radio-activity and animal tissues, 173

ROYAL ACADEMY OF MEDICINE IN IRELAND.—*Section of Anatomy and Physiology:* Exhibition of specimens, 1477—*Section of Medicine:* Bronzing of skin; Pigmentation in pernicious anæmia; Glycosuria following Graves's disease, 1002—Glycosuria and Graves's disease; Treatment of gastric ulcer, 301—Types of imbecility; Pseudo-hypertrophic muscular paralysis; Sciatica; Leukæmia, 723, 724—*Section of Obstetrics:* Fibroid myoma; Teaching of midwifery, 502—Myoma of uterus; Ovarian pregnancy; Painless labour, 28, 29—*Section of Pathology:* Bovine piroplasmosis; Exhibition of specimens, 1539—*Section of State Medicine:* Prevention of small-pox, 1352—*Section of Surgery:* Injuries of the brachial plexus; Operation for fractured femur in a child aged 4 years; Multiple bone tuberculosis two years after treatment; Fracture of humerus, 646—Malignant disease of the large intestine; Empyema of the ethmoidal cells, 177—Nephrectomy; Coxa valga; Ununited fracture of the tibia, 1413

ROYAL SOCIETY OF MEDICINE.—*Section of Anæsthetics:* Choice of the anæsthetics, 791—Lymphatism, 500—*Section of Balneology and Climatology:* Arthritis deformans, 859—Arthritis deformans; Climate of Egypt and North Africa and its influence on disease, 1201—Chiltern Hills; Atmospheric electricity, 27—Saline waters and the use and abuse of common salt, 501—*Clinical Section:* Exhibition of cases, 240, 859—Exhibition of cases; Aneurysm of the descending thoracic aorta, 571—Endothelioma of the tongue; Exhibition of cases, 1070, 1689—*Laryngological Section:* Exhibition of cases and specimens, 240, 500, 791, 1071, 1411—*Medical Section:* Pancreatic (Cammidge) reaction, 1475—*Medical and Surgical Sections:* Diagnosis and treatment of pericardial effusion 641—Duodenal ulcer, 169—Pericarditis with effusion, 719—Treatment of tetanus, 367—*Obstetrical and Gynæcological Section:* Abdominal hysterectomy; Cyst of the broad ligament, 26—Operation for prolapsus uteri under local analgesia; Hæmatoma of ovarian origin; Malignant and innocent ovarian growths, 369, 370—Place of Cæsarean section in the treatment of placenta prævia, 1271—Post-peritoneal hæmatocele complicating a uterine fibroid; Modern methods of delivery in contracted pelvis, 644—Ruptured tubal pregnancy; Contact carcinoma; Myomectomy, 859 — Cæsarean section in the treatment of eclampsia gravidarum; Life-history of fibromyomata of the uterus, 1688—*Odontological Section:* Odontoceles; Suppuration in the maxilla; Neuralgia due to impacted lower wisdom tooth; Exhibition of cases, 1203—*Pathological Section:* Gastric analysis; Pernicious anæmia; Amyloid degeneration in an adenoma; Primary carcinoma of the liver, 924—Serum diagnosis of syphilis; Grafting fœtal cartilage, 570—Thyroid and antithyroid preparations; Oöphorectomy; Pancreatic reaction in the urine; Caseation of adrenal capsules; Pigmentary deposits in liver and pancreas; Chylous cyst, 367—*Section for Study of Disease in Children:* Exhibition of cases, 721, 1202, 1537—Exhibition of cases and specimens; Cyclic vomiting; Infant feeding, 432—*Surgical Section:* Cancer of the pylorus, 498

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Cancer of large intestine; Exhibition of cases, 574, 1273—Intracranial tumours, 925—Streptococcus isolated from cases of acute rheumatism, 926—Medico legal aspects of asphyxia; Exhibition of specimens, 797

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Disinfectants, 862—Majority Report of Royal Commission on Poor-laws and Relief of Distress, 1141—Minority Report of the Royal Commission on the Poor-laws in its relation to public health and the medical profession, 241—Problems connected with the medical treatment of school children, 573

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—Latency of malarial infection; Typhoid fever prophylaxis; Fever with rash in the Yangtse Valley, 925

UNITED SERVICES MEDICAL SOCIETY.—Treatment of syphilis by intramuscular injection of metallic mercury; Notes on mercurial creams, 926

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Death of Mr. C. B. Keetley; Exhibition of cases, 302—Exhibition of specimens, 574—Treatment of brain tumours, 863—Exhibition of cases and specimens, 1139—Wassermann reaction in eye-work; Acute hæmorrhagic pancreatitis, 1619

WINDSOR AND DISTRICT MEDICAL SOCIETY.—Purpura; Exhibition of cases; Henoch's purpura, 302

Medical society, new social, in Toronto, 686

Medical Society of London, annual dinner, 830

Medical students, curriculum of, point of view of teacher (Dr. J. B. Hellier), 85, 115

Medical students in France in 1910, cosmopolitanism of, 1233

Medical students at University of Budapest, 74

Medical survey in the Philippines, 1099

Medical teaching, extension in Glasgow, 1101

Medicine, advancement of, by research (Earl of Cromer and Sir David Bruce), 1635

Medicine, of Ancient Romans (leading article), 1700; and atmosphere, 1705; Chinese, 411; Clinical, System of, dealing with Diagnosis, Prognosis, and Treatment of Disease (Dr. T. D. Savill) (review), 303; Dental (Manual of Dental Materia Medica, and Therapeutics) (Mr. F. J. S. Gorgas) (review), 1697; and education (leading article), 247; exercise in, 1165; Exercise in Education and Medicine, 1909 (Dr. R. T. McKenzie) (review), 1074; French Congress of, 1033; general, dermatology in relation to, 206; (leading article), 40; History of (Geschichte der Medizin) (Dr. M. Neuburger) (review), 1763; and Hygiene, Tropical (Dr. C. W. Daniels and Major E. Wilkinson) (review), 1762; internal, German Congress on, 1719; Internal Diagnostics of (Dr. G. R. Butler) (review), 1356; problems of embryology in relation to (Prof. P. Thompson), 1247; science and art in, 1115; Sixteenth International Congress on, 690, 875, 1634; social, development of (La Revue Médico-sociale), 1286; System of, by many writers, 1909 (review), 648; Theory and Practice of (Dr. F. T. Roberts) (review), 107; tropical, need for mathematic in, 1015; at World Missionary Conference, 1770

MEDICINE AND THE LAW.—Action against a medical man for the loss of a wife, 1710—Baby farming cases, 60—Brown *v.* Honan and others, 1492—Burning accident and the Children Act, 379—Butter adulteration and the sale of margarine as butter, 379—Certificates of the cause of death and future legislation, 1092—Charity Commissioners and the variation of charitable bequests, 1710—Dangerous quack, 452—Death due to ferro-silicon, 60—Falsely pretending to be a registered medical practitioner, 1493—Fraudulent use of the name of a medical practitioner, 581—"Hygienic institutes" mulcted in damages, 452—Impudent fraud, 817—Keogh *v.* Incorporated Dental Hospital of Ireland, 526—Liability of local authorities for unsuccessful prosecutions under the Public Health Act, 1875: Hobbs *v.* Winchester corporation, 1022—Medical men's attendance in midwives' cases: variants of the usual difficulty, 580—Poor man's lawyer movement and the medical profession, 816—Preservation of dead bodies with a view to identification, 1092, 1422—Question of responsibility for medical attendance, 1493—Registration of

a death due to a cause unknown, 1493—Sale of poisons and the name of the seller, 1222—Signing of a death certificate by an unqualified person, 1422—Unqualified dentist: conviction of police court set aside in the Irish Divisional Court, 452—Workmen's compensation and the form of a medical referee's certificate, 581

Poor-law medical relief, 941; reform of, 741
Poor-law Medical Service, 602, 681, 823; in France, 65; of the future, some speculations on (leading article), 655
Poor-law out-relief, administration of, 1590
Poor-law Policy (English) (Mr. and Mrs. Sidney Webb) (review), 578
Poor-law reform, Parliamentary discussion on, 1108; (proposed) some medical aspects of (leading article), 1766; scheme proposed by the Right Hon. Charles Booth, his views on care of the sick, 1158; in Ireland, 1504; scheme for, by Poor-law Medical Officers' Association, 670
Poor-law relief and Midwives Bill, 1572
Poor-law relief, children in receipt of, presentation of report to Parliament, 761; and Midwives Bill, 1164, 1226, 1299, 1500
Poor-laws and Relief of Distress, Royal Commission on, proposals in regard to medical relief made in, 1141; (review), 1694
Poor man's lawyer, movement and medical profession, 816
Population, difficulty of, accurate determination in districts, effect on vital statistics, 1363
Porcelain houses, 835
Pork, Chinese, 1661; importation of (Parliamentary question), 691, 900, 1178; in Isle of Man (Parliamentary question), 967; Parliamentary question, 1314; re-exportation ordered, 471
Porritt, Mr. N., clamps in gastro-enterostomy, 331; new operation for hæmorrhoids, 519; simple and efficient operation for hæmorrhoids, 360
Porter, Dr. C. A., and Richardson, Dr. O., tetanus bacilli in lymphatic glands, 314
Porter, Dr. F., discussion on rational puerperium, 372
Porturtle, 653
Post-graduate courses, International Committee for, 1084; lectures, 888
Postmen and infection (Parliamentary question), 1795
Post-mortem examination in public mortuaries, preparation of bodies for, 765; examinations, risks of, 682
Post-nasal space, tumour filling right side of, 1760; and pharynx, swab-holder for, 182
Post-office authorities' action in regard to measles, 1366, 1573, 1646, 1717, 1784
Post-Renaissance Period (late sixteenth and early seventeenth centuries), medico-missionary enterprise in, 337
Potassium (see Bichromate of pot[illegible]ium), 297
Potteries (The), Federation of th[illegible] Six Towns, comprising, 1500, 1575; healt[illegible] problems in, 1500, 1575
Pouches, pharyngeal, schema 1257
Poulain's cocoa, 307
Poultry, epidemic among, 8[illegible]
Powell, Dr. H. W. Fitzgerald, tumour filling right side of post-nasal space, 1760
Powell, Sir R. Douglas, discussion on systematic instruction in psychiatry (Royal College of Physicians), 729
Powell, Sir R. D., Laking, Sir F., and Reid, Sir J., authorised report of the last illness of His Majesty King Edward VII., 1380
Power, Mr. D'A., election of, as corresponding member of the Budapest Royal Society of Medicine, 1491
Power, Dr. F. B., and Moore, Mr. C. W., constituents of colocynth, 662
Power, Dr. F. B., and Salway, Dr. A. A., constituents of red clover flowers, 662
Power, Mr. H., "In piam memoriam," 398
Poynton, Dr. F. J., congenital family cholæmia or recurrent familial jaundice, 153; discussion on pericarditis with effusion, 721; some observations on infective arthritis, 1142; and Trotter, Mr. W., case of cardiolysis, 1690
Poynton, Dr. F. J., and Paine, Dr. A., some further investigations and observations upon the pathology of rheumatic fever, 1524
Practical jokes, foolish and dangerous, 1593
Practical Medicine Series, vol. iv., Gynecology (review), 376
Practical Medicine Series (review), 800
Pratt, Mr. J. E., note upon two cases of hæmorrhage following gastro-enterostomy with clamps, 923
Prayer Quest: a Physiological Extension (Dr. W. W. Hall) (review), 1006
Precipitin test in medico-legal work (Prof. E. J. McWeeney), 1669
Pregnancy, bacillus coli infection of urinary tract complicating, 1476; case of, complicated by acute intestinal obstruction, 647; complicated by infective endocarditis (Dr. E. E. Norton), 162; complicated by perinephritic abscess, 1353; jaundice of doubtful origin, with fatal termination occurring during case of (Dr. G. F. England and Mr. F. K. Thornton), 160; myomectomy during, 859; at seven months, complicated by appendicitis, 647; ovarian, specimen of, 28; ruptured cornual, 301; tubal, following external migration of an ovule, 335, 399; tubal, specimen of, exhibited, 1414; tubal, ruptured, 859; tubal, unruptured, of thirteen months' duration, operation and recovery (Mr. J. Morris), 1469; early tubal, diagnosis of, 211; tubal unruptured, advanced, 1563

Preliminary medical scientific studies, memorial to General Medical Council, 1554
Premiums for breast nursing of infants, 540
Pre-Rolandic cortex, structure and functions of, 1047
Presentations and testimonials, 690; to Prof. Bar, 136; to Dr. T. S. Clouston, 271; to Mr. B. G. Derry, 1238; to Dr. J. Fletcher, 1647; to Mr. R. A. Jones, 1743; to Dr. T. Gambier, 14; to Dr. R. Inch, 341; to Dr. J. S. Mather, 107; to Mr. W. Monckton, 544, 919; to Prof. A. Ogston, 959; to Mr. E. J. Parry, 1039; to Dr. W. Roulston, 277; to Prof. W. Roux, 1659; to Dr. A. Sheridan, 899; to Dr. D. H. Stirling, 1101; to Mr. J. J. Thomas, 919; to Dr. J. C. Thomson, 338; to Dr. Trudeau, 896; to Dr. James Whiteford, 71; to Mr. J. E. C. Wilson, 830
Press, public, of Canada, attitude of, in regard to secret nostrums, 137
Pressor bases of urine, further work on (Dr. W. Bain), 1190
Preston, freedom of borough conferred on Dr. R. C. Brown, 761
Preston Royal Infirmary, new wards at, gift of Dr. R. C. Brown, 409
Prevention of Destitution Bill, debate in Parliament on (leading article), 1076
Priapism complicating appendicitis, 470
Primates, pronograde, pelvic floor muscles in, 1459
Princess Alice Memorial Hospital, Eastbourne, 672, 1386
Principe, Island of, method of destroying tsetse flies in, 446
Pringle, Mr. Seton, case of complete transposition of the viscera, 1477; coxa valga, with the report of a case associated with ankylosis of both hips, 1413; discussion on nephrectomy, 1413
Printing, amateur, 1167
Prison Commission, constitution of, 1298; constitution of (leading article), 1213; Commissioner (medical) (Parliamentary question, 1794; medical member of, 1239; medical member of (Parliamentary question), 1240
Prison reform in Missouri, 896
Prisons, medical officers of, and Home Office, relations between, 120
Pritchard, Dr. E., and Stephenson, Mr. S., case of Basedow's disease in boy, 433
Privat-docenten, position of, at University of Berlin, 612
Privation, deaths from, in 1908, 1108

Stomach, cancer of, case exhibited after extensive double operation, 28; latent cancer of, with metastases in bone marrow and blood, suggestive of pernicious anæmia, 1562; classification of cases, 415; diagnosis by chemical and other methods, 417; diagnosis, value of gastroscope in, 418; early diagnosis, 533, 602, 752, 822, 888 (Mr. C. M. Moullin), 415; early diagnosis, successful operation dependent on, 415; early symptoms, 416; relation to ulcer, 415
Stomach, contents of, diagnostic value of chemical analyses of, after test meal (Dr. W. H. Willcox), 1119; Diseases of (Medico-Chirurgical Series, No. 2) (Dr. W. Cecil Bosanquet and Mr. H. S. Clogg) (review), 1274; Diseases of, 1909 (review), 726; diseases of, treatment by neutralon, 73; and duodenum, ulcers of, treatment of, without operation, 927; or duodenum, perforation of, 12 successive cases, with 11 recoveries (Mr. T. Carwardine), 239; and intestines, chronic affections of, systematic investigation (Dr. G. Herschell), 1401; and intestines, diseases of (Dr. R. C. Kemp) (review), 1763; ulcer of, treatment, 301; perforated ulcer of, in child, 809; perforated ulcer of, gastro-jejunostomy for, followed by two consecutive perforations of peptic jejunal ulcer (Dr. A. E. Maylard), 497; and suppurative appendicitis, simultaneous occurrence (Mr. C. A. Moore), 103, 119; removal of hair-ball from, by gastrotomy, 435; tetany originating in, fatal case, 1618; ulcer of, perforation of, or inhaled tooth, cause of case of pyopneumothorax (Mr. W. G. Nash), 236
Stoney, Dr. R. A., two cases of nephrectomy, 1413, 1528
Stonham, Mr. C., Birds of the British Islands, 1909 (review), 1420
Stopper, rubber sterilising, and modified urethroscope, 510
Strauss, Dr. L., centenary of Benedikt Stilling's birth, 1153
Street, Mr. C. T., treatment of mental disorder, 1353
Street accidents (metropolitan) (Parliamentary question), 1241; payment for attendance on, 610
Street dogs of Constantinople, 1580
Streptococci, acute infections of, use of vaccines in, 241
Streptotricheæ, biological relationship of parasites of tuberculosis to, 771; and certain acid-fast organisms not under parasitic conditions, habitat of, 773; infection of appendix cæci by, 630; infection of oral mucous membrane by 628; and Koch's bacillus, acid, fast staining properties of, 773; pathogenic-general biological characteristics of, 626; pathogenic for man, 626; position of, in botanical classification, morphology and method of reproduction, 552; species of, and parasite of tuberculosis, affinity between, 551; acid-fast, 769; parasitic, and pathogenic for higher plants, and animals lower than man, 555; saprophytic, 555
Streptotrichoses, general pathology, 627; primary, pulmonary, 630; and tuberculosis (Mr. A. G. R. Foulerton), 626, 769; (leading article), 802 (see also Streptotricheæ)
Strichen Hospital for Infectious Diseases, committee of inquiry appointed, 1722
Stridor, expiratory nature of, in bronchial asthma, 1499
Strong, Dr. R. P., and Teague, Dr. O., treatment of trypanosomiasis, 1228
Struthers, Mr. J. W., case shown after removal of spindle-celled sarcoma from brain, 1539
Strychnine, administration of, ending fatally, action against medical man for, 1710; employed in spinal anæsthesia, death from excess, 1288
Strychnine poisoning, first aid in, 902
Student's guide to medical schools of France, 46
Students of medicine, men and women, co-education of (leading article), 1423
Students' Union in Dublin, 335
Subinvolution, uterine treated by electricity, 350
Submarines, effect of, on eyesight, 1713
Submaxillary gland tumour of, 574
Subsidies (Government) for scientific research, 1630
Sudan, destruction of mosquitoes' larvæ by fish in (Dr. A. Balfour), 100
Suffolk, East, schools, report of school medical officer, 1438
Suicide, removal of larynx, four rings of trachea, and part of thyroid gland and gullet removed during act of, 792
Sulphates and ammonia, estimation of, in urine, 618
Sunderland, cholera at, with analysis of blood taken from patient (Looking Back), 124
Sunderland, Dr. S. P., discussion on arthritis deformans, 1201
Sunen, Dr. A. P., and Lavin, Dr. L. R., Fisiologia General, 1909 (review), 1622
Sunshine in Channel Islands, 399; in Guernsey, 131; and rainfall of 1909, 588
Superannuation allowances of vaccination officers (Parliamentary question), 1178; of asylum officers (Parliamentary question), 1178
Super-centenarian, 544; death of, 961
Superfœtation, specimen of, from cat, 1477
Superintendentship of Bristol City Fever Hospital, 1789
Superstition in Ulster, 1233
Suppositories, nutrient, 1234
Suprarenal capsules, extensive yet incomplete fibro-caseous disease of, in which symptoms of Addison's disease were not present, 368
Surgeons, certifying, and trades unions (Parliamentary question), 1795
Surgery, Abdominal, Contributions to (the late Mr. H. L. Barnard) (review), 798; Aseptic (Mr. C. B. Lockwood) (review), 800; Clinical, with Special Reference to Diagnosis and Treatment (Dr. T. Bockenheimer) (review), 374; Emergency, for General Practitioner (Dr. J. W. Sluss) (review), 1698; German Congress on, 1301, 1441; Manual of (Mr. A. Thomson and Mr. A. Miles) (review), 242; odds and ends in, 177; Operative, System of, by various authors (edited by Mr. F. F. Burghard) (review), 178; Operative, Vol. I., 1909 (Prof. J. F. Binnie (review), 929; practical and operative) appointment of lecturers in, at Leeds University, 958; Practi e of, 1909 (Mr. W. G. Spencer and G. E. Gask) (review), 437; Principles and Practice, 1909 (review), 576; Urgent (Prof. F. Lejars) (review), 1481
Surgery, Handbook of (Mr. F. M. Caird and Mr. C. W. Cathcart) (review), 1543
Surgical instruments, original makers of (disclaimer), 1298
Sussex County Hospital, Brighton, 689
Sutcliffe, Mr. H., A Winter's Comedy (review), 1420
Sutton Coldfield, borough of, report of medical officer of health, 1161
Sutton, Ringworm School of Metropolitan Asylums Board at, 54
Swab-holder for post-nasal space and pharynx, 182
Swainson, Mr. J. M. G., strangulated ovarian tumour removed from child aged two, 433
Swansea, pulmonary tuberculosis in, 70
Swansea Hospital, 1449
Swansea and Merthyr Asylum, 824
Sweet, Mr. E. H., post-graduate lectures, 888
Swindler, dangerous, 280
Swinton and Pendlebury urban district, annual report of medical officer of health, 1438
SWITZERLAND, CORRESPONDENCE FROM. — Medical curriculum in Switzerland, 273
Sydney Hospital, charge of neglect at, 139
Sylvan, Dr. F., Home Exercises for Health and Strength, 1909 (review), 109
Symbiosis, bacillus influenza and Dr. R. W. Allen), 1263
Syme, Mr. G. A., return of, to Melbourne, 897; chronic sphenoidal sinus disease, 422
Symes, Dr. J. O., fatal case of acute anterior poliomyelitis, 421
Symington, Prof. Johnson, skiagrams illustrating the development of the teeth in primates, and the relation of the teeth to the maxillary antrum, 1477
Symington, Prof. J., and Schäfer, Prof. E. A., Quain's Elements of Anatomy: Descriptive Anatomy of the Peripheral Nerves and of the Organs of Special Sense, 1909 (review), 1354
Symmers, Prof. St. C., lecture delivered by, on trypanosomiasis and sleeping-sickness, 1102
Symonds, Mr. C. J., case of rodent ulcer treated by radium, 1070
Synechiæ, congenital anterior with buphthalmos, 434
Synostosis, premature, 1593
Synthetic products, official recognition of, as expressed by inclusion in different pharmacopœias, 1638
Syphilis, acute visceral, resulting in permanent cardiac lesion, 646; of central nervous system, treatment, 1720; diagnosis (see Wassermann's reaction); discussion on (Royal Society of Medicine), 1757; fixation of complement of, in, simple method (Dr. J. Sabrazès and Dr. K. Eckenstein), 232; of heart, 503; hereditary and acquired, La Nuovo Scienza Medica Ossia la Sifilide Ereditaria ed Acquisita en Rapporto alle Malattie del Corpo Umano, 1909 (Dr. P. Tusco) (review), 1356; and marriage, discussion on, 174; notification of, 1582; secondary multiple phlebitis in, presence of spirochæta in wall of veins, 1428; serum diagnosis of, 570, 1072; System of, 1909 (review), 1353; treatment, comparative value of various methods of anti syphilitic treatment as estimated by Wassermann's reaction and clinical observation (Mr. C. Gibbs and Mr. H. W. Bayly), 1256; by intramuscular injection of metallic mercury, 926; by intramuscular injection of insoluble preparations of mercury as contrasted with inunction method, 129; and tuberculosis, difficulty of diagnosis between, 1772; by mercury and arylarsonate combined (Col. F. J. Lambkin), 23; use of arylarsonates in, followed by optic atrophy, 1690
Syphilitic disease of hypophyses, 274
Syphons, beer in, 281
Syringe, new, for delivering accurate volumes of tuberculins or vaccines, 1147
Syringomyelia treated by radium, 253

T

Tabes dorsalis, case with various complications, 796; with signs of early general paralysis, case of, 302
Table (see Operating table)
Tail, movements of, 1461
Talbot epileptic colony, 1311
Talipes, congenital, 1412
Tamworth Hospital, 401
Tandler, Prof., influence of the sexual glands on bodily development, 1172

Tannin, in tea, 1044; teapot for prevention of brewing, in tea, 902
Tarnowska trial, 1487
Tarsectomy, partial, for tuberculous disease, 1761
Tasmania, public health in, 897
Tattooing in Persia, 835
Taunton, health of, 892; meeting for consideration of care and control of feeble-minded held at, 471
Taunton and Somerset Hospital, abuse of charity at, 536; centenary year, 536
Tauszk, Prof. F., intestinal putrefaction in catarrhal jaundice, 337
Tawse, Mr. H. B., Killian's submucous resection of the nasal septum, 374; and Willis, Mr. W. M., case of growth blocking left nasal cavity, 798
Taxation of medical practitioners in Austria, 1444
Taylor, Mr. E. H., complete tear of the brachial plexus (shown by Mr. C. A. K. Ball), 646; operative treatment of malignant disease of the large intestine, 177
Taylor, Mr. G., case of volvulus associated with the reduction of a hernia, 1530
Taylor, Mr. G., and Lakin, Dr. C. E., perforative peritonitis originating in pouches of the large intestine, 495
Taylor, Dr. G. G. T., and MacKenna, Dr. R. W., spirochæta pallida, 1141
Taylor, Dr. J., lecture on some points in the diagnosis and treatment of certain nervous affections, delivered before the Hampstead Medical Society, 354
Taylor, Dr. J. G., and Lowe, Mr. W. F., faced rice as a danger to health, 1687
Taylor, Dr. J. W. (obituary), 687
Taylor, Mr. P. C. P., guinea-worm in unusual position, 1451
Taylor, Dr. S., case of tables dorsalis with signs of early general paralysis, 302
Taylor, Mr. W., specimen of hypernephroma removed from man, 1539
Taylor Memorial Home, proposal for, 1231, 1789
Tea, adulteration of, not widespread at present day, 1285; preparation of, 1514; tannin in, 1044
Tea gardens of Jailpaiguri and Duars, malaria in, 1310
Teacher, Dr. J. H., and Harrington, Dr. A. W., latent cancer of the stomach with metastases in the bone marrow and blood, suggestive of pernicious anæmia, 1562
Teaching, competitive, in University of Glasgow, 825
Teague, Dr. O., and Strong, Dr. R. P., treatment of trypanosomiasis, 1228
Teale, Dr. M. A., some difficulties in prescribing and wearing glasses, 1413
Teapot (anti-tannin), 902
Teapot "colander," 143
Tebuk lazaret on Hedjaz Railway, 891
Teeth of children, condition (Parliamentary question), 832; artificial, bestowal of, on inmate of Newton Abbot Workhouse, 1510; defective, in Navy, 831; of soldiers, care of, 752; (leading article), 656; responsibility of officers for cleanliness, 1099; (see also Cysts, dentigerous)
Teeth sockets, progressive destruction of (Mr. J. F. Colyer), 1258
Telangiectasis following radiotherapy, treatment of, 136
Telephone as aid to diagnosis, 1284
Telling, Dr. W. H. M., pernicious anæmia due to oral sepsis, 1349, 1350
Temperance in relation to medicine (La Revue Médico-sociale), 1286
Temperance movement in Ireland, 683
Temperature, variations of, in phthisis during menstrual period, 821; variations of, in phthisis during menstrual period (Dr. C. G. Welch), 639
Temperatures, increased, experiments on disinfecting powers of (Looking Back), 261
Temporal bone, infantile types and their surgical importance (Mr. A. H. Cheatle), 491
Temporo-sphenoidal lobe, island of Reil, and ventricles involved in encapsulated abscess (Dr. J. A. C. Macewen), 1533
Tents, ventilation of, in tropics, 1708
Teratology in Italy, 1044
Teratoma, remarkable, 1792
Territorial army nursing, 1714; and its sanitary corps, 254; sanitary service, 1714
Territorial Force Nursing Service, 461
Territorial hospital arrangements (Parliamentary question), 967
Territorial Medical Service, 805
Territorial Year Book, 1782
Territorials in camp, health of (Parliamentary question), 833
Testator, munificent, 1591
Testicle, lymphatics of (Dr. J. K. Jamieson and Mr. J. F. Dobson), 493
Testis, chorio-epithelioma of, case of (Dr. O. C. Gruner), 790; and epididymus, acute strangulation of, by torsion, two cases, 175; malignant tumours of bilateral origin, 427
Test meal, diagnostic value of chemical analysis of gastric contents after (Dr. W. H. Willcox), 1119
Test-types for Vision at Distance (Sehprobentafeln zur Bestimmung der Sehschärfe für die Ferne) (Dr. v. Ammon) (review), 1209
Tetanus bacilli in lymphatic glands, 314; toxin of, localisation in nervous system, 191; treated by atropine, 1430; treated with subcutaneous injections of magnesium sulphate, recovery, case of (Dr. P. Paterson), 922; treatment of, by intraspinal injection of solution of magnesium sulphate, 367; cephalic (Kopf-tetanus of Rose) (Mr. C. V. Kebbell), 1474
Tetany, gastric, fatal case, 1618
Teutonic and Latin races, defects of, 894
Theocol, 653
Therapeutic Agents of Bacterial Origin (review), 1006
Therapeutics: Materia Medica, Pharmacy, Pharmacology, and Therapeutics, eleventh edition, 1909 (Dr. W. H. Hale White) (review), 728
Therapeutist (electric), alleged, sent to prison, 281
Thermal stations of France, excursions for medical study, 1233
Thermo-generator (Davidson's), 1182
Thermometer, clinical, disinfection of, 901; clinical, for domestic use, 618
"Therol" electric water heater, 110
Thew, Mr. T. W., oral sepsis considered from a dental point of view, 1414
Thibierge, M. G., and Ravant, M. P., Multiple phlebitis in secondary syphilis, presence of the spirochæta in the wall of the veins, 1429
Thiele, Dr. F. H., some observations of the pathology of "pernicious" anæmia, 924
Thigh, upper third of, extraction of bullet and sequestrum from, ten years after injury (relic of Jameson raid) (Mr. H. Curtis), 992
Thirst and dyspepsia in light of osmotic pressure, 187
Thoinot, M., pupil midwives and professional secrecy, 1723
Thomas, Dr. C. J., increase of salary, 616
Thomas, Mr. J. Lynn, clamps in gastro-enterostomy, 677
Thomas, Mr. J. T., presentation to, 919
Thomas, late, Dr. Evans, 385
Thomas, Mr. W. T., discussion on duodenal ulcer, 436; and Mackarell, Dr. W. W., exhibition of (1) specimen of X ray dermatitis and epithelioma, (2) loop of small intestine, 796
Thompson, Mr. E. T., note on desiccated culture media, 1411
Thompson, Dr. J. A., leprosy in New South Wales in 1908, 1219
Thompson, Lady, death of, 1504
Thompson, Prof. P., the Arris and Gale lectures on some embryological problems in relation to medicine, delivered before the Royal College of Surgeons of England, 1247, 1321
Thomsen's disease, functional spasmodic contractures resembling, 28
Thomson, Dr. A. D. R., discussion on athletics and physical development, 795
Thomson, Prof. H. A., case exhibited after extensive resections in two operations for gastric carcinoma, 28; and Miles, Mr. A., Manual of Surgery, 1909 (review), 242
Thomson, Dr. H. C., case of cerebral tumour of the motor area, 374; case of paralysis of serratus magnus muscle from injury, 374
Thomson, Dr. J. C., presentation to, 338
Thomson, Dr. J. D., and Cushny, Prof. A. R., antimony compounds in the treatment of trypanosomiasis, 938
Thomson, Dr. StClair, complete inspiratory stenosis of the larynx, 792; four cases of epithelioma of the larynx after operation, 571; radical frontal sinus operation, 1412; removal through the mouth of a shawl-pin impacted in a secondary bronchus, 1264
Thoracic physics, 811
Thoracoplasty for very large empyema, 240
Thorax, congenital deformity of, 1141; congenital deformity of, in boy, 722; rigid dilatation of, operation for, 1285; stenosis and rigid dilatation of, operation for, 1302
Thorne, Dr. L. T., fatty degeneration of arterial hypertension, 1536
Thornton on Patents, 1910 (review), 801
Thornton, Mr. E. N., notes on the use of adrenalin chloride in the treatment of plague, 994
Thornton, Mr. F. R., and England, Dr. G. F., case of jaundice of doubtful origin, with fatal termination, occurring during pregnancy, 160
Thresh, Dr. J. C., and Beale, Mr. J. F., action of liquid kolynos upon the bacillus of influenza, 1406
Throat, diseases of, administration of Public Health and Education Acts in relation to (Mr. T. J. Faulder), 1746; Nose, and Ear, Diseases of (Text-book), 1909 (Dr. F. R. Packard) (review), 440; and Nose, Diseases of (Dr. C. G. Coakley) (review), 1481; Diseases of (Dr. E. S. Yonge) (review), 179; sore, defective ventilation a cause of, 809; Tuberculosis of Nose and Throat, 1909 (Dr. L. B. Lockard) (review), 33
Throat and Ear Hospital, Brighton, 299
Thrombosis, mesenteric, successful treatment by resection of intestine, 1085; of pulmonary veins and mitral stenosis in case of embolism of abdominal aorta (Dr. S. P. Phillips), 1065; of veins of penis in gonorrhœa, 449
Thursfield, Dr. H., and Branson, Dr. W. P. S., Medical Morbid Anatomy and Physiology, 1909 (review), 1209
Thymus gland, removal of, 1441
Thyroid and antithyroid preparations, action of, 367
Thyroid body, embryology of, 1247
Thyroid extract, case of rheumatoid arthritis treated by, 643
Thyroid gland, minute structure of (Dr. D. C. Watson), 1137; part of, with gullet, larynx, and four rings of trachea removed during act of suicide, 792; partial removal followed by laryngeal paralysis, 1760; rich protein diet in relation to, 435; tabloid, standardised, 308
Thyroid treatment of two cretins, 1539
Thyroidectomy followed by paresis of recurrent laryngeal nerve, 1441
Tibbles, Dr. W., bacterial disturbances of digestion and the consequences thereof, 503
Tibia, enlargement of tubercle of (Schlatter's disease), three cases, 1689; displacement of fibula on, in case of old-standing forward dislocation of foot, 1071; epiphyseal detachment of lower end of, and fracture of fibula, 336; ununited fracture of, treated by wiring, 1431
Tick, hereditary transmission of spirochæta Duttoni in (Sir W. B. Leishman), 11; Life Cycle of Piroplasma Canis in (Capt. S. R. Christophers) (review), 929
Tick fever, mechanism of infection in (Sir W. B. Leishman), 11
Tietze, Prof., operations for Little's diseases and other spinal diseases, 1302
Tillard, Mr., discussion on athletics and physical development, 795
Tilley, Mr. H., case of healed tuberculous laryngitis treated by galvano-puncture, 1071; fibrolysin in treatment of dry catarrh of the ear, 240; intratracheal and extratracheal masses of papillomata, exhibited, 1071; penny removed from the gullet, 1411; portion of mutton bone removed from right bronchus, exhibited, 1071; removal of a rapidly growing soft fibroma from the posterior wall of the left maxillary antrum by Rouge's operation, 792; vulsellum catch-forceps, exhibited, 1071
Tillystown, drainage of, 469
Tilmann, Prof., operations for traumatic epilepsy, 1301
Tinnitus, audible, 106
Tissues, action of radium upon, 1002
Tiverton, sewerage of, 1659
Tobacco factories, Austrian medical clubs connected with, 403
Tobacco smoke, hitherto unrecognised constituent of, 662
Tongue, base of, three rare tumours (two of them endotheliomata), 1070; entire excision of, 1411; inoperable carcinoma of, treatment, 1140; malignant disease, surgery of, 1070
Tonsil and palate, tumour of, case for diagnosis, 859
Tonsillitis, acute, prophylaxis and therapeutics of, 1306
Tonsils, faucial, surgery of, 1072
Tooth, inhaled, or perforation of gastric ulcer, cause of case of pyopneumothorax, drainage, recovery (Mr. W. G. Nash), 236; replacement of, by patient, after loss of from pyorrhœa alveolaris, 759
Toothache, alum in (Looking Back), 326
Toothbrushes for workhouse children, 1798
Torbay Hospital, Torquay, 1176
Toronto, cost of patients of, in city hospitals, 138; experimental station in, in connexion with Ontario provincial Board of Health, 275; meat-packing houses and abattoirs of, visit to, 331; new social medical society in, 686; University of, medical education in, 1103; Academy of Medicine, new home for, 1506; General Hospital, 686, 965
Town planning in Greater London, 1154; at Liverpool, 1718
Towns, large English, recent birth-rate and infant mortality in, 1151
Toxins of diphtheria and tetanus, localisation in nervous system, 191; putrefaction of intestine, action of bile upon, 210; Serums and Vaccines in Treatment and Diagnosis, 1909 (Dr. W. Cecil Bosanquet and Dr. J. W. H. Eyre) (review), 727
Trachea (four rings of), larynx, and part of thyroid gland and gullet removed during act of suicide, 792; method of direct examination of, by Brüning's instruments, 575; and œsophagus, case of communication between, 1308

Tracheotomy for foreign bodies in the air passages, 189
Trade unions and certifying surgeons (Parliamentary question), 1795
Training colleges, teaching of hygiene in, 1243
Transactions of the Ophthalmological Society of the United Kingdom, 1909 (review), 650
Transplantation of joints, 1442
Trattles, Mr. J., trial of his case for colour-blindness, 309; (leading article), 312
Traumatic subdural hæmorrhage (late) or traumatic late apoplexy, 463
Trébéron, French naval sanatorium at, 385
Trees (see Plane trees)
Trevelyan, Dr. E. F., habit spasm, 796; lymphatic leukæmia, 1141; tabes, 796; typical epilepsy in twins, cases exhibited, 372; and Allan, Dr. J., painful tonic spasm in the hands, 1141
Trevethick, Dr. E., case of lymphatism, 1717
Triangular cartilage, extreme deflection, with crests and adhesions and anterior prickle-shaped spur, treated by septal fissure, 1071
Trillat, M., and Sauton, M., impure air and putrid emanations, 1033
Trinidad Association for the Prevention and Treatment of Tuberculosis, 1607
Trinity College, Dublin, members of medical profession recipients of honorary degrees from, 659; pass lists, 828, 1038
Trional, poisoning by massive doses of, two cases with recovery (Mr. J. S. Mackintosh), 104
Triplets, interesting case of, 1619
Trommer's elixir, 653
Troops, British, in India, health of, 1709
Troops, Indian, new barracks for, 613
Troops serving in India, spectacles for, 759
Tropical diseases, investigation of, Parliamentary discussion on grant for, 762; King of the Belgians' grant for investgation of (Parliamentary question), 1315
Tropical Diseases Research Fund, 690; annual report, 738
Tropical medicine, 1031; Far Eastern Association of, first biennial meeting, 1227; school proposed for, in India, 1174
Tropical Medicine, Manual of (Dr. A. Castellani and Dr. A. J. Chalmers) (review), 1622
Tropical and Subtropical Climates, Personal Hygiene in, 1908 (Dr. J. W. Brewer) (review), 305
Tropics, diseases of, 897; Elementary Hygiene and Sanitation in (Dr. W. T. Prout) (review), 1208; ventilation of tents in, 1708
Trotter, Dr. Max, Where Knife is Driven, a Story (review), 34
Trotter, Mr. W., and Poynton, Dr. F. J., case of cardiolysis, 1690
Troup, Dr. J. M., and Maynard, Mr. G. D., modern statistical methods, 1336
Trudeau, Dr., testimonial to, 896
Truro board of guardians and the Midwives Act, 1511
Trypanosomes, development of, in tsetse flies, 1631
Trypanosomiasis, bibliography of, 117; treated by antimony compounds, 938; treatment of, 1228; human, new forms of, 1774
Tsetse flies, development of trypanosomes in, 1631; method of destroying, in Island of Principé, 446
Tubercle bacilli, sources of, in cow's milk, 1090
Tubercle of tibia, enlargement of (Schlatter's disease), three cases, 1689
Tubes, feeding bottles with, forbidden in France, 1306
Tubercular diseases of skin and their treatment (Dr. J. L. Bunch), 287, 316; infections, unity of, 770
Tuberculin, old, 1545; human and bovine, alternate use of, new method of treating acute phthisis (Dr. H. W. Crowe), 1130, 1154; ointment, Moro's, use in diagnosis of tuberculosis, 73; in treatment of surgical forms of tuberculosis (Dr. N. Raw), 844; varieties of, 941
Tuberculins, 845; diagnosis by, 846; new syringe for delivering accurate volumes of, 1147
Tuberculosis Act, working of, 1722
Tuberculosis, of bones and joints, sanatorium treatment of, adopted at Brighton, 455; in childhood (leading article), 185; of cold-blooded species, 770; compulsory vaccination against, in United States, 1581; conference on, date and place of meeting, 1706; death-rate, 1790; diagnosis of, by means of deviation of complement (leading article), 734; diagnosis and specific treatment of, 1719; diagnosis by use Moro's tuberculin ointment, 73; dispensary, 878; Exhibition in Liverpool, 1648; growth of dispensary movement, 880; future development of, 881; dispensary for Cardiff, 1503; early recognition of, 337; education in, 1235; exhibition, 1789; St. Pancras, 1055; extensive, of larynx with pulmonary tuberculosis, 500; ferment, treatment for, 685; fight against, at Manchester, 1377; First International Spanish Congress of, 1008; in Glasgow, 1232; hospital, infection of, 1376; as exemplified by records of resident staff of Mount Vernon Hospital, 1270; infection by anatomical inquiry into pathology of (Dr. F. W. Jones), 914; infection from, in health resorts, 1440; instruction on, in North Devon, 829; invalids in army for, 763; in Ireland, deaths from (Parliamentary question), 1794; laryngeal with dysphagia, relieved by venous congestion, 1760; treatment by alcohol injections into superior laryngeal nerve (Dr. J. Dundas Grant), 1754; among merchant seamen, 1309; and milk-supply in Birmingham, 608; of Nose and Throat, 1909 (Dr. L. B. Lockard) (review), 33; notification and treatment in Glasgow, 208; and other infections bacteriæmia in (leading article), 1212; Paddington dispensary for (leading article), 867; parasite of, and species of streptotricheæ, affinity between, 551, 771; parasites of, morphology, 772; part played by non-tuberculous meats in diffusion of, 1490; patients suffering from, attitude of family medical attendant towards, 557; attitude of hospitals towards, 556; percentage of samples of London milk showing tuberculous infection, 450; personal infection in, 548; problem of eradication of, 876; preventive treatment of, 878; public assistance of patients suffering from, 585; prevalence of, among school children, 751, 820, 886; "preventorium" for children, near New York, 75; propagation of, among children, 1308; of rat, 771; Registrar-General's annual report on, for 1908, 261; relation of fibrosis to (Dr. C. T. Williams), 1521; spread of, in Budapest, caused by insanitary conditions of lodging-houses, 337; and streptotrichoses (Mr. A. G. R. Foulerton), 626; (leading article), 802; Studies in (Dr. H. Clarke) (review), 864; surgical forms of, methods of infection, 845; and syphilis, difficulty of diagnosis between, 1772; treatment by tuberculin (Dr. N. Raw), 844; Treatise by American Authors, 1909 (review), 506; treatment of, by Marmorek's serum, 273; treatment of, use of light in, 274; use of eau-de-vie in connexion with prevalence of, 1428; avian, 770; bovine (see also Milk, tuberculous)
Tuberculosis, human and bovine, 771; relations between, 758; infantile, in Vienna, 1444; multiple, of bone, exhibition of case after two years' treatment, 647; pulmonary, action of Edinburgh town council with regard to, 757; in children (Dr. M. H. Williams), 1531; with extensive tuberculosis of larynx, 500; and family practice (Dr. H. Batty Shaw), 556; modern treatment (Dr. F. J. Wethered), 987; notification of, 471; Sanatorium treatment (Dr. D. J. A. C. Muthu) (review), 1145; Open-air or Sanatorium treatment of (Dr. F. R. Walters) (review), 1003; in Swansea, 70; variations of, during menstrual period (Dr. C. G. Welch), 639
"Tuberculosis-Sunday," 1309
Tuberculous abscesses of bony origin, treatment by conservative methods (Dr. H. J. Gauvain and Dr. J. Calvé), 633
Tuberculous children, schools for, 525
Tuberculous disease, partial tarsectomy for, 1761; of knee, case shown after excision for, 28
Tuberculous glands, treatment by X rays, 775
Tuberculous lesions, carcinoma supervening on, 316
Tuberculous ulceration of epiglottis, apparently healed by frequent use of electro-cautery, 1761
Tumours of bilateral origin, 680; malignant and non-malignant, of bilateral origin (Mr. W. R. Williams), 426, 515
Tunica vaginalis, rupture of, in hydroceles (Mr. S. Hastings), 916
Tuning-fork, Bárány's new tests by (Dr. E. C. Baber), 996
Tunstall, Dr. A. C., and Warwick, Dr. F. J., First Aid to the Injured and Sick, sixth edition, 1910 (review), 728
Turbinate, inferior, "bleeding polypus" of, 792
Turkey, conditions of admission to foreign medical men to practise in, 74
Turner, Dr. A. L., case shown after recovery from septic meningitis complicating chronic middle-ear suppuration, 28
Turner, Dr. D., rodent ulcer at the left angle of the mouth and nose, 1538
Turner, Mr. G. G., death from perforation of the aorta by a halfpenny impacted in the œsophagus, 1335
Turner, Dr. J., examination of cerebro-spinal fluid, 1621
Turner, Dr. J. A., malaria in the city of Bombay (leading article), 1281
Turner, Dr. P. D., abdominal hysterectomy 63 hours after labour for a necrosed and suppurating subperitoneal fibroid, 26
Turner, Mr. W., railway medical appointment to, 1728
Turner, Dr. W. A., and Stewart, Dr T. G., Text-book of Nervous Diseases, 1910 (review), 1206
Tusco, Dr. P., La Nuovo Scienza Medica, ossia la Sifilide Ereditaria ed Acquisita in Rapporto alle Malattie del Corpo Umano; Studii ed Osservazioni ad Uso dei Medici Practi, 1909 (review), 1356
Tweedie, Mr. A. R., congenital cleft of the whole soft palate, 792
Tweedy, Dr. E. H., antisepsis and asepsis in midwifery practice (leading article), 1148; modern methods of delivery in contracted pelvis, 644; modern methods of delivery in contracted pelves, 1344; single-handed attendance at difficult labours, 1026; specimen of ovarian pregnancy, 28
Twins, typical epilepsy in, cases exhibited, 372
Typhoid bacilli in gall-bladder, 211
Typhoid carrier, infection by, 794; release of, 896
Typhoid fever, carrier cases of, annual report of medical officer of Local Government Board concerning, 1021; commencing with lobar pneumonia, 9; in Constantinople, 613; decrease of, in city of Paris, 1233; in India, 1568; effect of flies on spread of, in India, 827; epidemic at Salonika, 75; in a hæmophiliac, 1288; in Hungary, 74; in infancy, 463, 531, 754; infant as carrier of infection of, 300; intestinal perforation in, simulated by perforation of a pyosalpinx, 385; outbreak of, in Madeira, 520, 589; in Madeira (Parliamentary question), 899; in Montreal, 137, 686; recent epidemic of, in Montreal, 1167; transmission of, by chronic carriers, 516; patients, flushing of, 663; prevention of, among soldiers arriving in India, 213; prophylaxis, problem in, and solution, 925; repeated occurrence of, at Jennet Hill and Stanford Dingley in rural district of Bradfield, 883; transmission of, by chronic carriers (leading article), 113
"Typhoid spine," case of (Mr. E. R. Carling and Mr. L. R. King), 1136
Typhoid vaccine, experiments with (Lt.-Col. D. Semple), 1751
Typhus exanthematicus in Budapest, 1103

U

Uganda, sleeping sickness in, 263
Ulcer (see Stomach, ulcer of, and under other regions, &c.)
Ulceration, axillary or thoracic, presence of, in cases of cancer, 978; of penis, 614
Ulna, subperiosteal resection of shaft of, for tuberculous osteomyelitis, 1761
Ulster, superstition in, 1233
Ulster Hospital for Children and Women, 960
Ulster Medical Society, 537, 684, 1232
Ultra-violet rays, practical sterilisation by means of, 937; sterilisation of water by means of, 1390
Umber, Dr., pathology of gout, 1721
Umney, Mr. J. C., and Hill, Mr. C. A., essential oils of the Pharmacopœia, 586
Uncinariasis (hook-worm disease) among white men in Philippines, statistical studies of, 1228; conference of, 895
Under-feeding of bottle-fed infants, 820
Unger, Dr., anastomosis of the facial and spinal accessory nerve, 611
Ungulates, pelvic floor muscles in, 1460
United Provinces, India, campaign against disease in, 1310; health of, 1725
United Services Medical Society, clinical meeting, 1507

UNITED STATES OF AMERICA, CORRESPONDENCE FROM.—Conference of the Hook-worm Disease (Uncinariasis) Commission; Suit for malpractice in the State of New York; Prevention of crime by treatment of defectiveness; Antivivisectionist campaign, 895—Testimonial to Dr. Trudeau; Honour to an octogenarian; Death of Dr. Follen Cabot; Release of a typhoid carrier; Prison reform in Missouri; What is Whisky?; Dietary of soldiers, 896—Important change in medical education, 1172—Banquet to Dr. W. H. Welch; Legislative control of the cold storage of foods; Summary of the anti-tuberculosis campaign; Medical men as expert witnesses, 1173—Suits for malpractice in leaving a sponge or pad in the wound; Education in tuberculosis, 1235—Commission on public safety; Cancer Research; Life insurance company and the attending physician; Sanitary condition of the Isthmus of Panama; Death of Dr. F. Bryon Robinson, 1445—Another martyr to science; Death of Dr. H. L. Burrell, 1506—Bubonic plague still a menace to the country; Tampering with the new pharmacopœia; Compulsory

vaccination against tuberculosis; Notable honours to a martyr to science and humanity, 1551—New medical centre; National Conference of Charities and Correction, 1652, 1653

Waters) (review), 1697
Universal service petition, 679
Universities, Scottish preliminary examinations at, 1504
University College, London, 544; lectures at, 1279; new chemical laboratories, 518, 1288
University College Hospital, treatment of ringworm by X rays at, 54
University Colston Society, annual dinner, 681; education in London (Parliamentary question), 1239; establishment at Hong-Kong, 445
University Intelligence, foreign, 77, 140, 215, 276, 340, 543, 567, 689, 740, 870, 899, 952, 1038, 1107, 1237, 1386, 1500, 1589, 1693, 1795
University, relation of, to medical school, 1309
University settlement, proposed, 1031
Upcott, Mr. H., clamps in gastro-enterostomy, 462; iso-hæmolysis in malignant disease, 795
Urachus, patent, and calculi encysted urinary (Capt. C. Dykes), 566
Uræmia, specimen of urinary organs from case after, with symptoms of, 721
Urban mortality, English, in 1909, 384
Ureter catheter, use of, note on use of (Mr. J. Clay), 238
Ureter, impaction of calculus in, causing large hydronephrosis, 1349; and renal pelvis, radiography of, 1632
Urethritis, acute gonorrhœal treatment of, in male, by passive congestion, 1350
Urethroscope, modified, and rubber sterilising stopper, 510
Urethrotome (see Maisonneuve's urethrotome)
Uric acid and sodium urate, solubilities of, 189
Urinary organs, specimen after death with uræmic symptoms, 721
Urinary tract, bacillus coli, infection of, 302; complicating pregnancy, 1476
Urine, chronic retention of, two unusual cases, 940; complete portable set of apparatus for rapid quantitative analysis of, 1698; composition of, significance of certain changes in, 503; drinking of, by hysterical woman (Looking Back), 1279; estimation of ammonia and sulphates in, 618; excretion of creatinine in, and electric bath treatment, 794; incontinence of, in women, treated by electricity, 352; occurrence of peculiar protein in (Dr. J. Henderson), 1069; "pancreatic" (Cammidge) reaction in, experimental investigation of origin and cause of, 368; pressor bases of, further work on (Dr. W. Bain), 1190
Urquhart, Dr. A. R., discussion on insanity as disorder of conduct, 1620
Uterine displacements, vaginal fixation in some indications for, 576
Uterus and appendages, specimen removed by abdominal hysterectomy for squamous epithelioma of vaginal portion of cervix, 1141
Uterus bicornis, 862; body of, in state of subacute metritis and double pyosalpinx, exhibited, 797; cancer of, radium in treatment of, 136; containing necrotic submucous fibroid, 647; containing papillary sarcoma of corpus and submucous cervical fibroid, exhibited, 797; containing submucous fibroid, partly sarcomatous, exhibited, 797; fibroid of, 301; case of post-peritoneal hæmatocele complicating, operation, cure, 643; traumatic rupture of, with intraperitoneal hæmorrhage, 647; fibromyomata of, contributions to life history, 1689; practical points in life history of, 1693; fibrosis of, specimen removed by vaginal hysterectomy, 1141; hypertrophied, 301; importance of removal of, in certain diseased conditions of adnexa, 862; malignant and non-malignant tumours of bilateral origin, 427; Myomata of (Dr. H. A. Kelly and Dr. T. S. Collier) (review), 1274; myomatous, with necrosis of one large tumour and carcinoma of endometrium, 28; pregnant, containing fibroid, 1142; prolapsed, carcinoma of cervix of, with contact carcinoma of vulva, 859; with severe cardiac disease, operated on under local and spinal analgesia, 369; removed by abdominal hysterectomy for fibroid tumour, 1413; rupture of, vaginal suture in, 519; treated by suture of the rent per vaginam and drainage, case of (Mr. H. J. Paterson), 497; subinoculation of, treated by electricity, 350; tumour of right broad ligament springing from, 27; unenlarged, hæmorrhage from, diagnosis and treatment, 501
Uvula and soft palate, malformation of, case exhibited, 1071

V

Vacancies, weekly lists of, 80, 141, 216, 279, 342, 409, 472, 545, 617, 692, 764, 834, 900, 968, 1042, 1110, 1180, 1242, 1316, 1388, 1450, 1512, 1592, 1660, 1731, 1796
Vaccination, annual report of medical officer of Local Government Board concerning, 1020; antirabic, 1791; in Bombay, 138; in Bristol, 892; compulsory, against tuberculosis in United States, 1581; compulsory Bill to abolish, in Ontario, 965; in Eastern Bengal and Assam, 76; in India, 1436, 1640; in Leicester (Parliamentary question), 1240; in the Punjab, 541; Smallpox and Vaccination in British India, 1909 (Maj. S. P. James) (review), 438; (Parliamentary question), 1794
Vaccination Act, 1907 (Parliamentary question), 1239
Vaccination officers, superannuation allowances of (Parliamentary question), 1178
Vaccinator, public duties of, 1514
Vaccine, new antityphoid, 684; prepared from cancer growth in treatment of cancer, 1228; staphylococcic, in treatment of multiple boils or abscesses in infants, 127
Vaccine therapy in treatment of four cases of gonorrhœal arthritis, 575
Vaccine treatment of lobar pneumonia, 809; of periodontal disease, 531; of periodontal disease (leading article), 443
Vaccine virus in Pharmacopœia, 541
Vaccines, 1545; bacterial, cases treated by injections of, 575; bacterial, hypodermic and intramuscular inoculation as demonstrated by experiments with typhoid vaccine (Lieut.-Col. D. Semple), 1751; new syringe for delivering accurate volumes of, 1147; in treatment of acne vulgaris, 1788; use of, in acute streptococcal infections, 241; and serums, value of, in treatment of disease, 861; and serums, Federal control of, in United States, 540; Serums and Toxins in Diagnosis and Treatment, 1909 (Dr. W. Cecil Bosanquet and Dr. J. W. H. Eyre) (review), 727
Vagina, primary epithelioma of, 796; suture of, in rupture of uterus, 519
Vaginal fixation in uterine displacements, some indications for, 576; outlet, relaxed, simple perineal operation for, 576
Valerobromine (Lagrand), 653
Valve, aortic insufficiency after rupture of, 612
"Vaporole brand" (see Inhaler, ammonium chloride)
Varicocele, ligature of spermatic artery in operation for, 588; and public services, 954, 1030; (leading article) 869
Varix, aneurysmal, in leg of child, aged 7 years, case of (Sir H. Morris), 1518
Vasectomy of defectives to prevent reproduction, 75
Vaseline, injection of, in treatment of dry arthritis, 1086
Vaso-motor and other phenomena associated with cervical rib, 1431
Vasotonin, 1720
Vaughan, Dr. E. I., problem in typhoid fever prophylaxis and the solution of the same, 925
Veale, Dr. R. A., and Hann, Mr. R. G., fatal case of poisoning by phosphorus, with unusual subcutaneous hæmorrhages, 163
Vein, results of punctured wound of artery through, 1519
Veins, microscopic structure of, 50; presence of spirochæta in walls of, in case of multiple phlebitis in secondary syphilis, 1428; resistance of, to progressive yielding under influence of blood pressure, 590
Veins and arteries, naked-eye difference between, 50
Von den Velden, Dr., operation for stenosis and rigid dilatation of the thorax, 1302
Veley, Dr. V. H., a dangerous dry shampoo, 1219, 1226
Venereal Diseases, History and Treatment (Dr. A. C. Magian) (review), 507; Social Disease and its Prevention (Mr. H. N. Robson) (review), 1543; in India, 1569; statistics of, in Germany, 1379
Venice, sailors' hospital at, 967
Venous congestion in relief of laryngeal tuberculosis with dysphagia, 1760
Venous œdema (see Œdema, venous)
Venous radicles, relation to lymph spaces, 1455
Ventilation, defective, a cause of sore-throat, 809; of tents, in tropics, 1708
Ventricles, island of Reil, and temporo-sphenoidal lobe involved in encapsulated cerebral abscess (Dr. J. A. C. Macewen), 1533
Verdon, Mr. W., comparison made between the simple gastro-circulatory seizure and the angina pectoris attack, 1679
Verney, Mr. H., accidents in factories and workshops, 313
Vertebræ, cervical, dislocation, case exhibited 28
Vertebrates, non-mammalian and pronograde mammals, evolution of pelvic floor in (Dr. R. H. Paramore), 1393
Vertigo, laryngeal, 500
Viala, M. J., antirabic vaccinations, 1791
Vicious circles associated with disorders of nervous system (Dr J. B. Hurry), 1197
Vickers, Dr. W., and Fairbank, Mr. H. A. T., case of enterectomy under spinal anæsthesia in an infant 7 months old, recovery, 364
Victor Emmanuel, King, at Messina, 1651
Victoria, Government of, provision for consumptives by, 1311; insanity in, 897
Victoria University of Manchester, pass-lists, 966
Victorian home for the aged and infirm, unsatisfactory condition of, 405
VIENNA, CORRESPONDENCE FROM.—Prophylactic measures against pellagra, 136—Suture of a penetrating wound of the heart; Treatment of exophthalmic goitre, 137—Syphilitic disease of the hypophysis; Refusal of payment for notification of infectious diseases by medical men; Murderous attack on a surgeon; Destruction of a hospital by subsidence and inundation; Use of light in the treatment of tuberculosis, 274—Medical clubs connected with the State tobacco factories; National expenditure for medical purposes; Physical care of children, 403—Unusual case of carcinoma of the pharynx; Painless childbirth; Distribution of the medical profession in Austria; Premiums for the breast nursing of infants, 540—Ferment treatment for tuberculosis; New radium spring in Joachimsthal; Sale of radium salt; Health statistics of labouring classes in Vienna, 685—Prevention of premature burial, 826—Memorials to Viennese physicians; A petition of the Vienna Medical Council about "social insurance," 827—Care of the feeble-minded; New director of gynæcological clinic; Questions of paternity decided by Wassermann reaction, 1034—Influence of the sexual glands on bodily development; Removal of a tumour of the hypophyses of the nasal route; Out-patients in the Vienna hospitals and dispensaries, 1172—Infantile tuberculosis in Vienna; Comparative chemistry of brain substance; Taxation of medical practitioners, 1444—Introductory lecture by Prof. Wertheim, 1445—Unique obstetrical event; Vienna General Polyclinic; Surgical treatment of "crises gastriques," 1652—Political parties and public health legislation, 1791—Remarkable teratoma; Treatment of congenital umbilical hernia; Late Prof. Zuckerkandl, 1792
